## TO MAINTAIN NORMAL PROTHROMBIN LEVELS

The complication of neonatal hemorrhage has been found to be abolished in infants born of mothers who have been given vitamin K during labor. Very significant differences have also been observed between the prothrombin levels of those mothers who had received vitamin K and the levels of the controls. For effective routine prophylaxis with vitamin K many physicians depend exclusively on Synkayvite 'Roche'. Synkayvite is a stable, water soluble vitamin K-compound—one and one-half times as active as natural vitamin K and of markedly low toxicity. Supplied in oral 5-mg tablets and 1-cc ampuls, 5 mg and 10 mg. . . HOFFMANN LA ROCHE, INC • NUTLEY 10, NEW JERSEY

***An effective vitamin K-compound***

*Casualties of nature's booby traps!*

# RHUS DERMATITIS

POISON IVY • POISON OAK • SUMAC

THE HOME FRONT—in particular gardens and outdoor areas—furnishes its share of minor injuries. Nature has skillfully planted “booby traps” of poison ivy, poison oak and sumac throughout many areas of the United States. In sensitive individuals the disabling dermatitis resulting from contact with these weeds may be prevented or treated with *Lederle* extracts in almond oil.

There is evidence to show that the same active principle is present in poison ivy, poison oak and poison sumac. It is possible to use extracts from poison ivy or poison oak interchangeably for immunization purposes. 1, 2, 3

*Literature will be sent upon request.*

#### PACKAGES

POISON IVY EXTRACT (in almond oil)

1 vial of 1 cc.

2 vials of 1 cc. each

POISON OAK EXTRACT (in almond oil)

1 vial of 1 cc.

7 vials of 1 cc. each

### as a Valuable Aid Before and After BILIARY TRACT SURGERY

When Decholin (dehydrocholic acid) or its sodium salt (intravenous) is given prior to surgery, the copious outpouring of thin liver-bile, secreted under increased pressure, makes bile ducts and gallbladder stand out prominently at operation, facilitating identification and manipulation.

Postoperatively, when external drainage is not employed Decholin tablets, usually tolerated after 48 or 72 hours, improve common duct drainage, aid in the removal of debris, reduce the discomfort. When drainage is used, Decholin hastens return of bile secretion, aids in disposing of inspissated bile, gravel, small stones overlooked at surgery. Contra-indicated only in complete biliary obstruction.

IN DISORDERS OF  
GASTRIC FUNCTION

*Gastron*  
REG. U.S. PAT. OFF.

GASTRON is an original extract of the organic and inorganic constituents of the entire mucosa of the hog-stomach, including the pylorus. The acidified and aromatized extract is incorporated in an aqueous-glycerin-propylene glycol menstruum which preserves the enzymatic activity. The preparation contains no alcohol. It is accurately standardized by assay.

GASTRON is indicated as replacement therapy in atrophic gastritis, and as an aid in the treatment of chronic gastritis. It is of value as adjunctive treatment in the anemias, and in certain gastric deficiencies associated with convalescence and old age. It is worthy of trial in the nausea and vomiting of pregnancy.

GASTRON WITH IRON also is available for prescription use

Originated and Made by  
**FAIRCHILD BROS. & FOSTER**

The Fairchild Buildings  
NEW YORK 13, N. Y.

The annual onslaught by pollens of ragweed, grass, burweed, thistle, cocklebur, is here, and the usual crop of allergic patients is seeking relief from the insomnia-producing symptoms of hay fever and asthma.

Curtalement of travel and increased employment rule out a large percentage of the yearly treks to regions where allergy patients formerly found freedom from symptoms.

*air-borne*

—a distinct advance in allergy therapy— enables the physician to offer relief from the sneezing, coryza, nervousness and general misery suffered by the allergy patient.

Amodrine is a new type of antihistamine, acting on the histamine mechanism of the body, and thus relieving the symptoms of allergy.

on respiration and its aid in allaying apprehension and nervousness.

Amodrine is supplied in bottles of 100 and 1000 tablets, plain or enteric coated.

## "FLYING MACHINES"

Remember the days when people scoffed at the dreams of a few men dreams of the average American taking to the air? Year by year, increasing numbers of travelers no longer chained to earth by fear and ignorance whisk through the air and accept it as a regular part of life.

There were days, too, when people avoided MARGARINE. But that was yesterday. Fortified MARGARINE'S present vitamin A content, its

nutritious American fats which provide the important unsaturated fatty acids, plus its increased palatability, sweetness, freshness and ease of digestibility have made it an outstanding nutritious spread and cooking fat.

Prejudice against Fortified MARGARINE is as ridiculous as would be a prejudice against the modern airplane, for this energy producing food is part of the seven basic food groups needed for good nutrition.

## NATIONAL ASSOCIATION OF MARGARINE MANUFACTURERS

MUNSEY BUILDING  
WASHINGTON, D. C.

Seal indicates these statements are acceptable to the Council on Foods and Nutrition of the A. M. A.

1 pound of MARGARINE provides wholesome easily digested vegetable oils and/or meat fats of American origin together with a minimum of 9,000 I. U. of vitamin A. Each batch undergoes numerous tests for quality and stability.

# HAVE YOU PATIENTS With Any Of These Conditions?

Spencer Abdominal Supporting Corset shown open revealing inner support. This is a SEPA-RATE section, adjustable to the corset section and the patient's figure by means of flat tapes that emerge on outside of corset.

When you prescribe a Spencer Support you are assured it will meet your specific requirements and the patient's figure needs, *because* it will be individually designed, cut and made for the one patient who is to wear it.

Every Spencer Support is individually designed for the patient of non-elastic material. Hence, the support it provides is constant, and a Spencer can be—and IS—guaranteed NEVER to lose its shape. Spencer Supports have never been made to *stretch to fit*; they have always been *designed to fit*. Why prescribe a support that soon loses its shape and becomes useless before worn out. Spencers are light, flexible, durable, easily laundered.

For service, look in telephone book under "Spencer Corsetiere" or write direct to us.

# *Smoother Relief*

## in HEARTBURN and NAUSEA of PREGNANCY

In the light of modern evidence, the heartburn of pregnancy derives—not from a gastric hyperchlorhydria—but rather from a spasm of the cardiac sphincter of the esophagus\*

Along with nausea of pregnancy, it is thus classified as essentially a neuromuscular disorder, calling for effective spasmolytic therapy

Donnatal—a compound of phenobarbital with predetermined and controlled proportions of the belladonna alkaloids—proves particularly helpful in these often difficult cases, since it—

Affords all the advantages of natural belladonna alkaloids—  
**YET IS SIGNIFICANTLY NON-TOXIC;**

Provides for the sedation so frequently required—  
**YET IS ENTIRELY NON-NARCOTIC; AND**

Has marked pharmacologic potency—  
**YET COSTS LESS**

It actually costs about half as much as synthetic preparations—even less than tincture of belladonna and elixir of phenobarbital

Formula: Each tablet contains belladonna alkaloids (hyoscyamine, atropine, and scopolamine) equivalent to approximately 5 min tr belladonna; plus 1/4 gr. phenobarbital

Available in bottles of 100 tablets

**A. H. ROBINS COMPANY, INC.**

# DONNATAL

**THE DEPENDABLE ANTI-SPASMODIC AND SEDATIVE**

## Measuring Results in Arthritis Therapy

The Grip Dynamometer is employed routinely as a measure of muscular function. One of the earliest signs of response to Ertron therapy is an increased strength of muscular activity.

The measure of effectiveness of anti-arthritic medication includes an appraisal of its effect on systems other than the articulatory system.

Thus, such responses as increased appetite measured by weight gain, and improved muscular action measured by ability to grip or lift, are evidence of systemic therapy in a systemic disease.

# ERTRONIZE THE ARTHRITIC

To *Ertronize* the arthritic patient, employ ERTRON in adequate dosage over a sufficiently long period to produce beneficial results. Gradually increase the dosage to the toleration level. Maintain this dosage until maximum improvement occurs.

*Ertronize* early and adequately for best results.

**ERTRON\*** alone—and no other product—contains electrically activated, vaporized ergosterol (Whittier Process).  
Supplied in bottles of 100 and 500 capsules.

**ETHICALLY PROMOTED  
NUTRITION RESEARCH

# SOPRONOL Inhibits FUNGOUS INFECTIONS

**MONILIA**  
albicans

**EPIDERMOPHYTON**  
Inguinale

**MICROSPORUM**  
audouinii

**TRICHOPHYTON**  
purpureum

... As demonstrated by clinical investigation  
in a leading United States hospital

In tests on a large number of hospital patients, Sopronol was found to exert an *inhibitory* rather than a destructive action on the fungus. The advantages of this method are obvious. Sopronol, taken readily into the fungous organism, prevents its development and spread. Hence the infection is quickly brought to an end, but without the customary skin irritation caused by poisonous by-products resulting from strong fungicides in contact with the mold. The chemical basis of Sopronol is sodium propionate.

## ALL SUPERFICIAL MYCOSES (RINGWORM)

Prescribe Sopronol for: Tinea Pedis, Tinea Cruris, Tinea Capitis, Tinea Glabrosa, due to "the dermatophytes"—Trichophyton, Epidermophyton, Microsporum, Monilia (Candida) and pathogenic aspergillae infections. Sopronol is non-irritating, non-keratolytic, non-toxic.

Available in alcoholic solution, powder  
and water soluble ointment bases

# WHEN THE *Body Rebels* AGAINST THE DICTATES OF THE YEARS

The natural estrogenic substances, parenterally administered by the physician, not only appear to be more effective in overcoming adverse menopausal symptoms, but contribute psychotherapeutically by necessitating personal contact with the physician. Semestrin, derived from pregnant mares' urine, hence containing estradiol as well as estrone, proves as economical as it is effective, in the menopausal syndrome, gonorrheal vaginitis in children, senile vaginitis, frigidity.

## SEMESTRIN

Semestrin, in 1 cc. ampuls is available in the following potencies: 2,000; 5,000; and 10,000 International Units; 2,000 International Units per cc. in 30 cc. vials, and 10,000 International Units per cc. in 10 cc. vials.

# *Summer Heat . . .*

## *Phagocytosis . . .*

### *Protein Need . . .*

The efficacy of phagocytosis is definitely linked to adequate protein intake. As environmental temperature rises, the diet-percentage of protein apparently must rise proportionately, to maintain phagocytosis at optimum.\* Meat is a rich source of proteins, and its proteins are of highest biologic quality, the RIGHT KIND for every bodily need, including phagocyte activity.

The Seal of Acceptance denotes that the nutritional statements made in this advertisement are acceptable to the Council on Foods and Nutrition of the American Medical Association.

\* Commenting editorially on the work of Mills and Cottingham (J. Immunol. 47:503 [Dec.] 1943), THE JOURNAL states: "They found that after five and one-half weeks maintenance at 68 F. rats showed a maximum phagocytic activity on diets containing 18 per cent of protein. There was a definite decrease in phagocytic activity with an increase or decrease from this level. In rats maintained at 90°F. the phagocytic optimum diet was 36 per cent of protein. Thus adequate protein intake would seem to be fully as important as adequate vitamin intake to maintain optimal phagocytic activity (resistance to microbic infections). The immunologic optimum protein intake is higher in the tropics than in temperate climates. . . . This demonstration of important variations in phagocytic functions is a pioneer contribution to basic immunologic theory and may have wide clinical implications." (J.A.M.A. 124:1203 [April 22] 1944.)

## *Treating the Patient* IN HYPOCHROMIC ANEMIA

The nutritional deficiency which frequently causes hypochromic anemia is rarely restricted to iron alone. Insufficient iron intake usually is linked with deficiencies of other nutrients vital to blood normalcy. But whether the anemia is caused nutritionally or by blood loss, a vicious cycle generally comes into operation: Anemia engenders anorexia and hypochlorhydria, thus inhibiting adequate intake and absorption of needed nutrients; their lack, in turn increases the

severity of the anemic state. In therapy, to aim at the iron deficiency alone means to treat merely a symptom; treating *the patient* calls for more complete measures.

Heptuna provides not only an adequate amount of highly available iron but, in addition, the fat-soluble vitamins A and D, and the B-complex vitamins (partly derived from a vitamin-rich liver extract and yeast) for optimal iron utilization, for promotion of appetite, and for improved endurance.

## Remember when you didn't believe in signs?

No healthy boy in his right mind ever let a sign interfere with a good swim. Nor have poison ivy or poison oak ever drawn back from his bared skin to let him enjoy that swim without any unpleasant after effects.

However, those youngsters who are susceptible can find a definite measure of protection in 'IVYOL' poison-ivy extract; and 'IVYOL' has decided value in the treatment of Rhus dermatitis as well as being a prophylactic agent. It has been clinically demonstrated that it is of definite benefit in relieving the irritating symptoms of ivy and oak poisoning.

'IVYOL' poison-ivy extract contains purified principles of poison ivy (1:1000) in sterile olive oil.

Administration by deep, intramuscular injection is relatively painless because of the bland vehicle.

Developed by the Mulford Biological Laboratories of Sharp & Dohme and accepted by the Council on Pharmacy and Chemistry of the American Medical Association, 'IVYOL' extract is supplied in packages containing one or four 0.5 cc. vials, each vial representing a single dose.

**Sharp & Dohme, Philadelphia 1, Pa.**

**PROPHYLAXIS:** Contents of one vial, intramuscularly, each week for four weeks.

**TREATMENT:** Contents of one vial, intramuscularly, every 24 hours until symptoms are relieved.

## DIETHYLSTILBESTROL

### *Reference Standard of Estrogen Effectiveness*

WITH the confirmation of findings of Dodd and his associates that diethylstilbestrol possesses estrogenic properties in amazingly small dosages, that it is highly effective when given orally, that its toxicity is low in therapeutic quantities, and with the realization of its low cost, a new standard of estrogenic effectiveness was established.

Since then, other synthetic estrogens have been announced and derivatives of various natural estrogens have been introduced. In nearly every instance when reports of these later studies have appeared, one generally finds therein reference to activity, toxicity, relative freedom from side-effects, and cost of the new preparation compared with diethylstilbestrol. Thus far no subsequent preparation has surpassed Dodd's original synthetic estrogen in all these criteria.

Diethylstilbestrol Squibb is available in a variety of dosage forms:—tablets for oral administration; solution in oil for intramuscular use and as vaginal suppositories. It offers

convenient, effective estrogenic therapy at very low cost. Thus thousands of women at a critical time in their lives may have the advantages of hormonal therapy which for economic reasons was previously restricted to a few.

For physicians who prefer naturally occurring estrogenic substance unmodified by hydrogenation or esterification, Amniotin in Oil is available in capsules for oral administration, in 10-cc. vials for intramuscular use and as vaginal suppositories.

### A Presidential Greeting

*"To the Ladies of the Woman's Auxiliary to the Medical Society of the State of New York.*

Greetings, and a pledge of real interest and co-operation!

"Do you talk to your husband about his county society meeting? You know it occurs on a regular stated date, from four to ten times a year. The county medical society is the foundation stone of Organized Medicine and by the same token it is the foundation of our present system of modern medical care. In medicine we strive for personal service and family consultation—right here is where you come into the picture—to see to it that the doctor in your family gets to his county medical meeting! For if he doesn't do that—really, now, how much good can you do in the Woman's Auxiliary? You have become acquainted with the influence that organization on sincere principles can have for the good of the public health. Against the white light of our truth and ideals, properly displayed, no one can long delude the American people with false propaganda on medical and hospital care. See that your husbands attend their county society meetings!"

"Did you ever think what a 90 per cent attendance at the county society medical meeting would mean to the community—especially to the officials of government who make, execute, and interpret our laws?"

Thus Herbert H. Bauckus, President of the Medical Society of the State of New York, spoke to the wives of the doctors at the 1944 Annual Meeting.

"When comparatively few members regularly attend, there is altogether too much work and responsibility placed on the few and pretty soon there arises the idea that mostly cliques run the affairs of medicine. This business of the practice of medicine extends deeply into the far realms of our social life—it is a complex problem indeed—it cannot be

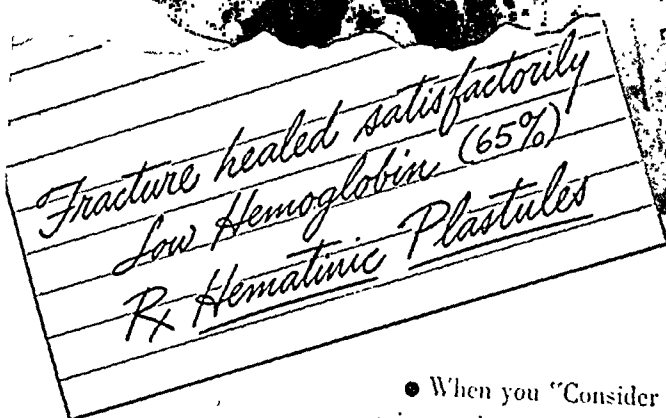

properly done by the few. We are a democracy first and last, as an example of adherence to the principles on which this great country developed its love and respect for liberty the medical profession stands among the most faithful. Our doctrine of free choice of physician—is it not just that?"

Just now, especially now, has it become evident to educators and the top scientific men of medicine that the selection of good medical students, high educational requirements for the graduate in medicine, high standards for the active practitioner are directly the responsibility of Organized Medicine, as is also legislation protective of the public health, legislation against cultism and quackery, antivivisection, antiscrum, antivaccination laws, the establishment of high standards embodying the formation of specialty boards, and the rating and inspection of medical schools and hospitals. The health of the worker is guarded as it could be under no other system, by our participation in the Workmen's Compensation Act.

"When someone, and he may be a doctor, attempts to belittle our organization, tell him some of these things. Our principles have been salutary for the human race since long before the time of Hippocrates, and when people have temporarily departed from them they did not do so well for themselves."

"I want to make it clear that even if your doctor doesn't always attend or support his county society he benefits from it just the same, and so do his patients!"

"The State Medical Society sponsors many excellent programs in the various parts of the State. These keep the physicians abreast of the most important newer advances in medicine and surgery. The Society has scientific district branch meetings annually in eight areas, and assists any county society in preparing a program in any of the departments of medicine. It sends its JOURNAL twice a month to all its membership, including those in the military services. It has an annual meeting at which topics of broad interest are presented to the

"Did you ever think what a 90 per cent attendance at the county society medical meeting would mean to the community—especially to the officials of government who make, execute, and interpret our laws?"

Thus Herbert H. Bauckus, President of the Medical Society of the State of New York, spoke to the wives of the doctors at the 1944 Annual Meeting.

"When comparatively few members regularly attend, there is altogether too much work and responsibility placed on the few and pretty soon there arises the idea that mostly cliques run the affairs of medicine. This business of the practice of medicine extends deeply into the far realms of our social life—it is a complex problem indeed—it cannot be

properly done by the few. We are a democracy first and last, as an example of adherence to the principles on which this great country developed its love and respect for liberty the medical profession stands among the most faithful. Our doctrine of free choice of physician—is it not just that?

"Just now, especially now, has it become evident to educators and the top scientific men of medicine that the selection of good medical students, high educational requirements for the graduate in medicine, high standards for the active practitioner are directly the responsibility of Organized Medicine, as is also legislation protective of the public health, legislation against cultism and quackery, antivivisection, antiserum, antivaccination laws, the establishment of high standards embodying the formation of specialty boards, and the rating and inspection of medical schools and hospitals. The health of the worker is guarded as it could be under no other system, by our participation in the Workmen's Compensation Act.

"When someone, and he may be a doctor, attempts to belittle our organization, tell him some of these things. Our principles have been salutary for the human race since long before the time of Hippocrates, and when people have temporarily departed from them they did not do so well for themselves.

"I want to make it clear that even if your doctor doesn't always attend or support his county society he benefits from it just the same, and so do his patients!

"The State Medical Society sponsors many excellent programs in the various parts of the State. These keep the physicians abreast of the most important newer advances in medicine and surgery. The Society has scientific district branch meetings annually in eight areas, and assists any county society in preparing a program in any of the departments of medicine. It sends its JOURNAL twice a month to all its membership, including those in the military services. It has an annual meeting at which topics of broad interest are presented to the

practicing physicians. It encourages the writing of scientific papers based on original study and in this respect has been the proving ground for many of the leaders of medicine.

"The parent organization of all county medical societies is the American Medical Association. It publishes the *Journal of the A.M.A.*, the most comprehensive and democratic medical publication in the world today. The A.M.A. maintains a most valuable educational bureau also. If the doctor will read the *Journal of the American Medical Association* and the *NEW YORK STATE JOURNAL OF MEDICINE* regularly, and will attend faithfully the clinics, lectures, and demonstrations provided by his county, State, and national organizations, he will keep himself in the best informed class of medical practitioners. That is just what you want, isn't it? I think it is about what everybody wants except the radical social philosophers who have the urge to revolutionize present-day medicine. I imagine our voluntary education programs irk and annoy them. And we didn't just start those programs since we heard of the Wagner-Murray-Dingell bill—you can read about our educating one another in the Oath of Hippocrates.

"We are trying to have a better understanding with the public, too. Committees of your county and State Societies are meeting with many lay groups interested in the general problems of this

complicated life. The A.M.A. publishes *Hygeia* so that people, children and adults, will better understand health. Medicine also has radio programs that tell the truth about health and disease. No one can gainsay that we do not try sincerely to prevent the diseases from which we make our living.

"Your husband, the doctor, will greatly help his community if he goes regularly to the hospital staff meetings. This is voluntary education, too—it is one effective way of teaching the doctor. For you know the doctor must ever be taught both the old and the new—sometimes the distinction is not a difference. The conduct of a hospital is to a large extent a medical problem. In spite of the urgency of his active practice the doctor should also maintain a lively interest in hospital management. Almost all hospital cases originate in the home call or the office. The physician then continues the care of his patient under the advantages of the hospital. But don't forget the word 'continues.' It is important.

"Well, good ladies, we can't stand too much improvement all of a sudden. But we can stand up with the boys and attend our own county medical society meetings.

"See to it that we do just that. Will you?"

"HERBERT H. BAUCKUS, M.D.  
President, Medical Society  
of the State of New York."

## Independence Day

Physicians, prominently among others, used to be concerned with the establishment and maintenance of civil liberties and the rights of the individual. Benjamin Rush perhaps typifies for us the American physician of the Revolutionary period of our history, to whom, with others of the signers of the Declaration of Independence, we owe the present tenuous enjoyment of our now somewhat abridged civil rights.

We are again about to celebrate Independence Day. It follows, in this third year of our participation again in a war of liberation, D Day, June 6, 1944. In the invasion of Europe and in the fighting all over the world American physicians, young and older, are serving their country with the armed forces. At home, the rest are serving industry and the civilian population to the limit of their ingenuity and their capability. In the Congress and in the various state legislatures some—perhaps too few—physicians are laboring politically to secure to the people such remnants of their individual rights as total war, political ambition, unwarrantable seizure of power by the Federal government, and the people's indiffer-

ence have not yet swept away. Shall their labors be in vain?

This year of 1944 is fraught, in our view, with the danger of losing at home what we fight for abroad. The winds of our destiny are blown with straws. It is time, if ever, to speak, as, at the time of this writing, our troops are committed to action in Europe. It is fitting that the occasion for this writing should be Independence Day, 1944.

The newspapers of June 5 and 6, soon to be notable days in our history, contain the following significant items:

"Washington, June 5.—Many people are going to be asked soon to decide whether the country will be any better off under Republican than Democratic rule. If the record as a whole of the Republican Party in Congress thus far is to be taken as a criterion, maybe the country will decide to settle down to a continuation of the Democrats.

"For the Republicans have stood idly by while civil rights have been taken from the citizen. They have failed to use their power as a minority to secure the liberties which they will presently tell the people the Democrats are taking away.

"There is, for instance, the simple matter of court review of acts of the executive agencies. Here is an issue of transcendent importance. It's an issue

any child who has studied our form of government can understand. . . ."

Thus David Lawrence<sup>2</sup> speaks on the subject of the decision of the U.S. Circuit Court of Appeals that War Labor Board orders are not reviewable by the courts. This is of significance when we consider the increasing number of medical activities which are under the control of executive agencies, both State and Federal.

As medicine pushes with vigor its medical expense indemnity insurance plans we read:

"Washington, June 5.—The Supreme Court, up-setting a 75-year-old decision, ruled today in a 1-to-3 opinion that the insurance business may constitute interstate commerce and is, therefore, subject to Federal regulation under antitrust provisions of the Sherman Act and under the National Labor Relations Act.

"The decision in the antitrust case was reached on a government appeal from an action by the Federal District Court for Northern Georgia dismissing Federal antitrust proceedings against one hundred and ninety-six stock fire insurance companies operating in six southeastern states—a case which brought Attorney General Francis Biddle personally before the Supreme Court for the only time this term. The decision paves the way for similar Justice Department actions already planned against other companies.

"However, congressional attempts specifically to exempt insurance companies from interstate commerce regulation will be pushed with renewed vigor, in view of the Supreme Court's decision, it was made clear in congressional and other quarters this afternoon."

From the May 15, 1944, issue of this JOURNAL we reprint in part the threat to medicine as "private enterprise" of the implications of the recent Montgomery Ward case.

"The recent seizure by the government of the Montgomery Ward Company, a concern which, to the ordinary mind, is not one producing munitions or war material of any kind, seems indicative of the attitude of government toward private enterprise in general.

"In that a certain portion of the institution of medicine still remains 'private enterprise,' it is directly concerned in this case, and in its outcome. As Mark Sullivan says:

"Much depends on whether the people—the average man and every man—can be made to see how far and deep the Ward case goes. To do this calls for re-education of our people in principles of govern-

ment and law and individual rights—principles so long taken for granted that the average person has come to think of them as a part of the permanence of nature, like the weather and the rotation of the seasons.

"A new generation of Americans must learn that these principles had to be established by struggle and now must be defended by vigilance."

And from the same issue<sup>5</sup> we note again the report of the American Bar Association's Committee on the medical and hospital provisions of the Wagner-Murray-Dingell bill:

"The bill fails to safeguard the rights of patients, citizens, hospitals, or doctors with respect to disputes arising or rights denied through the arbitrary or capricious action of one man.

"The bill fails to provide for any appeal to any court from the action of the Surgeon General.

"The vicious system whereby administrative officials judge without court review the actions of their subordinates in carrying out orders issued to them is extended in this bill to a point foreign to our system of government and incompatible with the adequate protection of the liberties of the people. . . ."

We note the hostile attitude of some of the press toward medicine in the matter of the report of the Moreland Act Commission, and its failure to credit the profession with the overwhelmingly honest and efficient medical service to injured workmen under the Workmen's Compensation Act in this State. In effect, this was a trial of the profession by publication and indictment, and not by due process of law—a sorry spectacle.

We note again the significance of the arbitrary action of the Children's Bureau of the Department of Labor in the matter of maternity and infant care for soldiers' dependents.

Who is to combat these cancerous erosions of civil liberties, this arrogant domestic trampling upon the rights of the people? The medical and some lay publications are doing what they can. The pitifully few representatives of the profession in Congress and the State legislatures are attempting to dam the flood with too few and too inadequate fingers in the leaking dike. But the winds of our destiny, laden with these cited and other straws, are piling up the waters dangerously behind the leaking dam of our Bill of Rights.

Independence Day, 1944, will have decreasing significance for us hereafter unless every physician, every citizen, every uneasy taxpayer exerts his utmost vigilance, makes his wishes heard by his representatives, and snaps out of his indifference as to what is happening under his very nose.

What is a man profited, if he shall gain the whole world, and lose his own soul?

## Immunity and Body Proteins

The belief is gaining ground that antibodies are globulins specifically modified so as to counteract the noxious properties of specific antigens.<sup>1</sup>

Further proof has been gathered that antibodies are elaborated by the macrophages, which are an integral part of the reticulo-endothelial system. While still attached to the parent cell, these immune bodies are called sessile antibodies. When produced in superabundance, the sessile antibodies have been shown to be shed by the macrophages into the circulation as floating or circulating antibodies ready for mobilization at any site where they are most urgently needed.<sup>1</sup> Blood rich in specific antibodies has proved to be of great value prophylactically or therapeutically, as in the instance of convalescent serum.

Since antibodies are probably modified globulins, their synthesis is linked with globulin formation. Mounting evidence indicates the dependence of the formation of immune bodies upon the synthesis of proteins from amino acids. Deficiency of body protein may be due to starvation, dietary insufficiency, metabolic diseases such as nephrosis, disorders of the liver, or to diseases which interfere with the absorption of adequate nutritive elements, as is frequently encountered in chronic intestinal diseases.<sup>2</sup> Such protein impoverishment may be reflected in a serum protein subnormal qualitatively and quantitatively,

which it now appears is a striking index of impaired resistance to infection.<sup>1-3</sup>

The cellular factor of immunity resides in the phagocytes and their capacities of phagocytosis. It is significant and striking that phagocytic powers are also impaired in a protein-poor organism.<sup>4</sup> Vitamin deficiencies also tend to create a similar decline in phagocytic powers and antibody formation. In depressing environments, such as the tropics, the need is great for maximal protein and vitamin intake, which must be optimal if adequate immunity is to be maintained.

The proof is accumulating that reserve stores of protein, vitamins, and other essential nutrients are the building stones of the bulwarks against infection. Immunologic studies continue to confirm the physiologic aphorism enunciated by Graham Lusk many years ago: "Functional activity of living matter is primarily due to arrangement of proteins in protoplasm." The problem is related to war and famine, for optimal nutrition of the masses is the basis of resistance against plagues and epidemics which at such times threaten to spread throughout the world.

## Military Surgeons to Meet

The program for the Annual Meeting of the Association of Military Surgeons of the United States to be held at the Pennsylvania Hotel, New York City, November 2 to 4 inclusive is being rapidly completed. In addition to addresses by the Surgeons General of the Army, Navy, and U.S. Public Health Service and by other distinguished guests, there will be formal papers, panel discussions, and scientific and technical exhibits on the latest advances in military medicine.

### Afternoon Session

May 8, 1944

#### Section 50

#### Report of Reference Committee on Report of Planning Committee for Medical Policies

**SPEAKER BAUER:** Ladies and Gentlemen, the Planning Committee for Medical Policies happened to be under my chairmanship; therefore, I don't deem it either fitting or proper that I should be in the Chair while this report is being considered. I will, therefore, yield the gavel to the Vice-Speaker.

**DR. JOHN J. MASTERS, Kings:** Mr. Vice-Speaker and Members of the House, I want to apologize for the length of this report. I wish I could read it by title, but that is not possible. However, I am not going to read the entire report as submitted by the Committee, because I assume that the delegates have already read it. We have tried to brief it as much as possible.

A careful reading of the report of this Committee shows they have given much thought and study to the important problems confronting us at this time. They deserve our congratulations for their excellent work and for the clearness and conciseness of their report, considering the number and importance of the subjects covered. In fact, nothing relating to the practice of medicine and our relations to the hospitals, industry, nursing, voluntary medical insurance, and medical education has been omitted from their report.

The report covers the following subjects, and we will discuss them in that order:

1. General Comments on Problems Involved
2. Compulsory Sickness Insurance
3. Wagner-Murray-Dingell Bill
4. Hospital Insurance and Medical Service
5. Regional Centers for Diagnostic Aid
- 6.
- 7.
- 8.
- 9.
10. Continuance of Committee

the cost. The Committee concludes there is no one answer to the problem and anyone who has given much study to the subject must agree with them.

Certain groups stress the need for medical care among the poorly housed, clothed, and fed section of the population, using the economic situation of these people as an argument for the overthrow of our system of medical practice, overlooking the fact that the removal of these economic barriers should be an end in itself and not used as an argument for a different system of medical care.

2. **Compulsory Sickness Insurance.**—The first

compulsory Gibbs Bill, State in 1911. In many countries, but nowhere has it given as high a level of medical care and of health as exists in the United States. The poor wages and lower standards in many countries, United States is very, most parts of the world. It is difficult to understand why some people are so insistently urging compulsory insurance just because it is in operation in other parts of the world.

Compulsory sickness insurance is mass production. The report and the quality of the work has been constantly improved, but there is ample evidence that the quality would degenerate under the compulsory plan.

3. **Wagner-Murray-Dingell Bill.**—So much has been written about this bill that it is unnecessary to

ness insurance in general, and disapproval of the Wagner-Murray-Dingell Bill. We approve of their recommendation.

4. **Hospital Insurance and Medical Service.**—less includes expenses Nursing care, (3) Medical and surgical service.

For the horizontal patient the last item is usually the smallest. The first two should be covered by prepayment plans for hospital care and the latter two by medical expense indemnity insurance. It would probably be a money-saving investment for

doctors' services.

Your Committee concurs with the action of the American Medical Association in opposing such services as pathology, radiology, anesthesiology, and any other medical service in a hospital insurance plan, and proposes that such services be insured for under a medical care plan.

The Committee is wholly in accord with the extent to which medical services should be covered. The reasons which were adopted by the House of Dele-

gates of the American Medical Association in June, 1943. It feels that these medical service features properly belong in a medical expense indemnity insurance plan.

With reference to the use of the insurance principle in the case of welfare patients, it is recommended that the Council suggest to the Welfare Department that it consider the possibility of the use of the insurance principle rather than the present system. We approve of the recommendation.

5. *Regional Centers for Diagnostic Aid.*—The Committee has made a very comprehensive study of the necessity of the location and the supervision of the centers in rural areas. They believe they can be created and operated in carefully selected areas with no damage to a free and unfettered practice of medicine. Since no specific recommendations are made at this time, we will not go into the details of their report. They do, however, recommend that a special committee or subcommittee be appointed by the President to make a survey of New York State to determine the need for such a program and the areas to be cared for. The suggested methods of operations are, of course, tentative, and if the survey indicates the desirability of establishing such diagnostic centers, then the details of management would have to be worked out carefully. Your Reference Committee recommends the appointment of such a committee by the President.

6. *Industrial Medicine.*—Industrial medicine, with all of its possible ramifications in the future, deserves and even demands immediate intensive study and cooperation by Organized Medicine to the end that this relatively recent special field shall not become a problem child.

The Council on Industrial Health of the American Medical Association has done a vast amount of constructive planning in this field, and has set up carefully planned programs for committees on industrial health, not only in the various state societies, but also one for the county society.

The program of the American Medical Association for state and county societies is carried in detail in the Planning Committee's report, so it is unnecessary to go into the details of this program at this time.

It may be truthfully said that if an active committee in the county medical society carried out in full the program recommended for such a society, it would result in far-reaching benefits to the industry, to labor, and to Organized Medicine. The innumerable problems that arise, involving the interests of each group, would have a common meeting ground where these might be resolved by cooperation and education. Farsighted policies could be outlined that would result in satisfaction to industry and labor and a true authority to Organized Medicine in matters of health.

We urge the State and various county medical societies to give particular attention to this rapidly growing field of industrial medicine so that it will not become a problem child on our hands. The Planning Committee recommends that the Committee on Public Health and Education increase the time allotted to industrial medicine in its education program. Since at the present time there is a definite shortage of physicians trained in industrial medicine, the State Society Subcommittee on Industrial Medicine is urged to stimulate the activity of county society committees in carrying out the above program of the American Medical Association, and to form committees in areas where they are needed. The State Department of Labor has been doing a splendid piece of work in this field, and it might be

increased and extended if the medical staff of the Department of Labor were increased so that members might assist county society committees in coordinating their work with the definite work of the Department. It is recommended that the Council bring this matter to the attention of the proper state authorities.

The Long Island College of Medicine in Brooklyn gave a course in industrial medicine in 1942 and 1943. These courses were well attended, and we would recommend that the Committee on Public Health and Education urge the other medical colleges in this State to consider the establishment of such courses. We request the approval of the recommendations in this part of the Report of the Planning Committee.

VICE-SPEAKER HALE: You have all heard this portion of the report of the Reference Committee, which is largely informative. If there is no objection, I will entertain a motion that it be accepted so far.

DR. GEORGE W. KOSMAK, *New York*: I so move. . . . The motion was seconded, and as there was no discussion, it was put to a vote, and was unanimously carried. . . .

7. *The Nursing Problem.*—DR. MASTERSON: The Committee believes that a more general understanding on the part of physicians of the problems of the nursing profession will result in mutual benefit to both the nurse and the doctor. In support of this belief it may be added that the Committee has explored the possibility of better understanding on such subjects as nursing educational background and training of the nurse, and whether a differentiation on this basis will ease the burden of the high cost of nursing care. These are subjects which have been studied and which concern the medical profession vitally.

Because the destiny of the medical profession is allied with that of the hospital, and that of the hospital with the nurse, it is imperative that a relationship which recognizes the interdependence of the physician, hospital, and nurse, be established. It appears possible, if too great an error is made in bringing together these three services, or if the correlation does not meet with public approval, that one or all of the services may suffer by the encroachment of public control through government or insurance channels. It is apparent that the leaders of the nursing profession recognize this trend as a possibility. They are at this time concerned also because there is a trend in nursing away from the professional toward the vocational status.

(In other words, now a large majority of the nurses immediately upon graduation or a short time thereafter go into industrial medicine, or into the public health service, the county health service, and the State health service, and so forth, so that is one of the reasons for the shortage of nurses at this time for really professional nurse service.)

This is the only part of the Report of the Planning Committee that we shall read in full:

"Members of the New York State Nursing Council for War Service have expressed a desire to have a planning group within the nursing profession which might work with a medical committee in studying the changing order.

"It is, therefore, the opinion of the Planning Committee that a continuation of the study of the changing trend in nursing in relation to medicine be authorized, and that during the coming year, now that the contacts have been made, a closer and more active exploration of the field be

made by joint meetings with a committee representing the nursing profession and, if possible, one representing hospital administration."

**8. Medical Education.**—As war measures, certain fundamental changes have been virtually forced upon medical education. Army and Navy training programs in general have been planned to provide training for the largest possible number of men in the shortest possible time. It is apparent that the present wartime program not only handicaps a student during his medical course and subsequent hospital training but brings him into the medical

The Committee feels that it is of the utmost importance that careful attention be given to the re-establishment of satisfactory standards of educational programs just as soon as the war needs will permit. This does not mean that the medical schools should blindly follow their prewar programs. On the other hand, the present upset in medical education programs offers opportunity for careful evaluation and postwar planning by the individual

deplors the apparently various states not only to the healers of the healing art to treat the public but to grant them full licensure for the practice of medicine and surgery.

The Planning Committee recommends that this section of the report be referred to the Committee on Public Health and Education, and we approve of that recommendation.

A more detailed report on medical education was prepared by Dr. Herman G. Weiskotten, who was

one interested in the subject. We recommend that the report of Dr. Weiskotten also be referred to the Committee on Public Health and Education.

I so move.

The motion was seconded, and as there was no discussion, it was put to a vote, and was unanimously carried.

**9. Voluntary Medical Insurance.**—DR. MASTERSON: The American people desire and demand a plan or plans for the prepayment of medical care costs. This demand must be met.

The Committee feels that voluntary medical insurance is one of the answers to this demand. The principle of this type of insurance has been approved by the American Medical Association and by this

experience has been accumulated. Two of the rea-

"Educate physicians of New York State by means of the JOURNAL and other publications.

"Report regularly to the Council and to the Committee on Public Relations and Economics.

"Make available material for the Publicity

"Meet with county societies in which no plans are operating, to the end that New York State may be wholly covered by voluntary prepayment plans.

"Meet with Departments of Social Welfare and Insurance and other official agencies of the New

"Meet with representatives of the Hospital Association of New York State and with the Hospital Insurance or Blue Cross organizations.

"Study and report on commercial insurance plans and policies.

"Meet with industry, labor, management, that is sponsoring medical care programs.

"Establish a control bureau as a clearing house for existing plans.

"Study possibilities and procedures for a statewide plan directed and controlled through the Medical Society of the State of New York."

(Some job! I don't think they ought to tell the duties of the man for this job until after they have hired him.)

personnel to Council.

Bureau in view

the war it would not be possible to establish such a Bureau

with proper financial support within the dues income of the Society without cutting down on some of the

other necessary activities. This is an emergency for which our general funds are available; and it is

recommended that for the period of the war the financial support of this Bureau should come out of

funds other than the general dues income, if the Trustees find it necessary.

Report of the Finance Committee

Your Committee concurs in the recommendation

as

director with the necessary personnel, and whose

duties are enumerated in the report. The selection of the director and personnel to operate this Bureau

shall be made by the Council, and the Board of Trustees should appropriate the money necessary for the establishment of this Bureau.

We further suggest that the Director of this Bureau should be thoroughly conversant with insurance practices, and should be a physician if possible.

therefore, urges the House to authorize the reappointment of the Committee on the same basis as

last year, namely, that it consist of the President, President-Elect, the Secretary, the Speaker, the

Chairman of the Board of Trustees or a member of the Board designated by him, and six members to

the necessary personnel. The Committee recommends following duties:

"Correlate the activities of the American Medical Association, other states, and other countries.

be appointed by the Speaker, the Committee to elect its own Chairman and Recorder.

We recommend continuance of Committee, and this is signed by the Reference Committee consisting of Harry V. Bull, Peter M. Murray, Stephen R. Monteith, Warren Woodpep, and John J. Masterson, Chairman.

I move the adoption of the report as a whole.

.... The motion was seconded. ....

VICE-SPEAKER HALE: We will have to take that last part in two actions. The first has to do with the matter of the establishment of a Bureau of Medical Care Insurance by the State Society. Is there any discussion on that?

DR. HARRY ARANOW, Bronx: I feel that before adopting this motion the thing should be thoroughly considered by the House. This will impose a considerable cost upon the Society. There is something peculiar about bureaus, on which we have had experience in many phases of our government, both national and State, in that when a bureau once gets engrafted in a place it is pretty hard to root it out. You are going to start another bureau by this action that is requested to do something which even made the Chairman of the Reference Committee, when making the report, say, "That man will have some job," or words to that effect.

I have had the good fortune of being on committees studying the various types of preventive insurance ever since the study was first made by the Committee on the Costs of Medical Care. I have been on both State and local committees, including that of the Academy. I am also a member of the Trustees of the C.M.C., the Community Medical Care, which is a medical insurance plan. We know that throughout the United States countless counties have tried to get the thing started, and in their zeal have had a tendency to oversell it; however, for some reason or another, there is not one in the whole United States that has made a tremendous success of it. The reason they have not is that there are some very serious drawbacks. The most serious drawback of all is that the people won't buy it. (Laughter)

The Community Medical Care has at its command the sales force of the Associated Hospital Service. The Associated Hospital Service, as you know, has a trained selling personnel, yet we find we cannot sell insurance to people; they are not interested except in large groups where the employer is willing to pay the cost.

The second problem is getting the doctors interested and really cooperating in it. We are all anxious about what this Wagner-Murray-Dingell bill is going to do that is detrimental to the future of medicine, but when it comes right down to the doctors personally there are very few of us who take an active part in doing anything about it. We have been trying to educate the medical profession in this county and all the other counties throughout the country about the importance of doing something; but have they done anything? No, they have not. There is not a more energetic and more serious and hard-working man than Fred Elliott, in Brooklyn. There is hardly a week that goes by when I don't get a letter from him appealing to the medical profession to help, and unless I am mistaken he got very little help from the medical profession.

It is very discouraging, I can understand that; and I can also understand the feeling of helplessness on the part of the Committee, so "Therefore, let us do something. We have got money in the Treasury, let us waste it or spend it, whatever may

be the result. We are going to get a man to do this job. He will have to be a man who understands insurance."

That is all very well and good, and sounds fine, but we will have to pay him a good salary if he is a good man. He will also have to have the medical concept. He will have to understand the practice of medicine, and I know for a fact that unless you practice medicine you don't get that conception. I have been in groups of medical men who practiced medicine higher up and who did not have the right conception of medical practice. So we are going to get that kind of a man, who has the medical conception, and he will have to educate the public and educate the medical profession, which we have tried to do for years and have not succeeded, to buy and sell this type of insurance.

I, personally, feel that such a man does not exist. I, myself, do not know anybody who would fill the bill, and I don't know whether you realize what you are doing when you give that as an order to the Council, as well as to the Board of Trustees, to do something which they may not be able to do. They might not be able to get the man, and if he is going to be a medical man, and you take him out of his practice and put him on a salary, you have got to support him for the rest of his life, because if he gives up his practice, after five years he cannot go back to it. Therefore, that is another matter you have to weigh: If you take a medical man out of his practice for five years, you have to support him for the rest of his life.

I consequently would suggest that this whole matter be left to the Council to decide whether the thing is possible. Let us express our sentiments that we are in favor of organizing such a Bureau, but, personally, I don't think the thing is possible.

VICE-SPEAKER HALE: We are discussing that part of the Planning Committee for Medical Policies' report which recommends the formation of a Bureau of Medical Care Insurance by the State Society, and the reference Committee has approved of that. Is there any further discussion?

DR. BENJAMIN M. BERSTEIN, Kings: Mr. Speaker, ladies and gentlemen, let us pray! Let us pray for the courage to withstand that which we cannot change. Let us pray for the farsightedness to see and the willingness to change that which we can change. Let us pray for the wisdom to know the difference between that which we cannot change and that which we can change.

Are we going to stand by again and see the march of progress pass us by and leave us far behind? Are we going to repeat the mistakes of former years when we first opposed compensation medicine in New York State, and then we took it so close to our hearts that we were loath to give it up. We opposed marriage between the Associated Hospital Service and Medical Expense Insurance, and you heard me read a resolution a little while ago that one of the organizations *sub rosa* proposed by the Associated Hospital Service has merged with Medical Expense Fund to organize a new medical service company.

If we don't take steps today—this is not a threat; I don't have to threaten you, for I threaten myself when I do—if we stand by and don't do anything at all about trying to sell some voluntary form of insurance, we are going to have compulsory health insurance thrust upon us whether we like it or not.

The other night Congressman Celler, in coming home to Brooklyn with me from a meeting in New York, said, "I don't think the Wagner bill is going

to pass this year, but don't forget the pattern we have followed, particularly in the past. Compulsory health insurance has been a success in Britain, and we are going to have it too some day, particularly when things are not as good as they are at the present time."

How are we going to counteract that sort of a trend, unless we try by all the efforts at our command to sell first some voluntary form of health insurance?

Let me tell you a secret. When the Medical Expense Fund in Brooklyn was established, I did not own it. I did not give them a dime because I did not feel that I would be willing to join the plan under which my fee would be a matter of what was left over, where I would have to compete for my own patients and then have what was left. But you heard me say this morning that the United Medical Service has cash in the bank to pay its bills and will make every attempt to pay all bills in full to every man that he gains by trying to purchase insurance for people above a certain income level, and service for those below who cannot afford to pay, those who today are our dispensary patients, those who today don't pay us even when they come to our office but shamefacedly leave a dollar bill behind on the way out.

If we don't establish a bureau for coordination and correlation, we will never have a State plan. In our own backyard.

Well, perhaps a State plan must come with local modifications to suit the local needs of each county and each community, but if we don't cooperate with each other, and don't coordinate our experiences, and don't have a man at our command who can go from hamlet to hamlet and sell this idea throughout the State, then we will not be able to sell it.

and keep him  
k into practice  
good? I don't  
think we will find a man of that kind at all in medicine.

I think we will find such a man now connected or associated with one of the insurance companies. I don't want to mention names, but there are men in the Metropolitan Life Insurance Company, in the Equitable Life Insurance Company, and other companies, who I am sure would possess sufficient knowledge of insurance problems to tackle a job of this kind, so we won't have to decapitate a man from his practice at all and then throw him back into the lap of the gods.

I plead with you let us have this Bureau now.

- want  
to say a word about the cost. We have heard it said that this will cost a lot of money. I think it will. However, I happened to read the Treasurer's report, from which I note that we have a surplus of over \$400,000, and that in spite of all the dire predictions of the previous Treasurer as to the effect of the war we have had an increased surplus balance this year of \$43,477.

This is an organization which lives on its members' dues, and theoretically it collects dues for the benefit of the members. It does not collect dues for any purpose of building up any wealth which might be thought of as a mortmain, and which might even later on be lost because of inflation or some

other measure. If we don't spend our members' money, we have no right to collect it.

Speaking about what money can do, in Westchester County we had a medical society for many years which was very inoperative, and did very little. Some ten or eleven years ago some of our leaders were farsighted enough to see that nothing would ever be done unless it was correlated, coordinated, and centralized in one person's office. They, therefore, at the expense of considerable disapprobation at the time, hired a full time secretary.

I think this body knows what has happened to Westchester County since then. I certainly can assure you that for a very pitayune price and with a very small increase in dues work has been accomplished which was never dreamed of before.

In my opinion, if we are ever going to lick this business of prepaid medical care we are going to have to be willing to dump into the pot some of this hoarded gold which came out of our pockets, and which is being built up for I don't know what reason—perhaps, to pay the dole to us when we no longer can make a living. (Applause)

VICE-SPEAKER HALE Is there any further discussion?

DR. THOMAS M. D'ANGELO, *Queens* Mr. Speaker and Members of the House of Delegates, I have the utmost confidence and respect for Dr. Aranow's judgment. I also have the utmost confidence in and respect for the judgment of the Council and its Board of Trustees. As I understand this resolution, all it asks is that the Council and the Board of Trustees may open such a bureau.

CHORUS No "Shall" is the word. It is mandatory.

DR. D'ANGELO Is that right?

VICE-SPEAKER HALE "Shall" is the word. It is

again?  
VICE-SPEAKER HALE Read it good and loud so all the delegates are able to hear it.

DR. MASTERSON "Your Committee concurs in the recommendation of the Planning Committee for the establishment, as soon as possible, of a Bureau of Medical Care Insurance by the State Medical Society under a full time director with the necessary personnel and whose duties are enumerated in the report. The selection of the director and personnel to operate this Bureau shall be made by the Council, and the Board of Trustees should appropriate the money necessary for the establishment of this Bureau."

DR. D'ANGELO I will still say that I don't see where it is mandatory, as read. All it provides there is that the Council shall, after a decision is arrived at, find the personnel to operate the Bureau and the Board of Trustees shall appropriate the funds, but I don't see where it says in that recommendation that they must open up such a bureau.

VICE-SPEAKER HALE If they can't do it, that is another thing, but if it is possible, they must do it.

DR. D'ANGELO Because it is discretionary, I think it is. This provides for a Board of Trustees.

I cannot find a man to head such a bureau it won't be opened. If during the year such matters should arise as would make such a bureau no longer be feasible, then I know they would not do it. This would leave it to the judgment of the Council and Board of Trustees, and

I would certainly recommend the adoption of this resolution.

VICE-SPEAKER HALE: Is there any further discussion?

DR. ABRAHAM KOPLOWITZ, *Kings*: Mr. Speaker, Ladies and Gentlemen, personally I think that you are going to pass this resolution. I hope so. But I don't want to take a chance, so I want to put two words in it, or more. I also have a lot of respect for Dr. Aranow, but I certainly could not respect his judgment on this question. Dr. Higgons, who reminded us about our reserve monies, has raised a question that a lot of us have been thinking about. What in heaven's name are we keeping that money for? For what earthly purpose except to buy bonds, and when the market falls to lose the money?

Now we are being faced with a situation where the people will demand and are demanding some form of medical expense insurance, either compulsory or voluntary. Unless we are hypocrites, we must do something about it. We keep on saying that it is up to medicine to lead the way, but just as soon as a plan is mentioned that means we are actually to do something, then there will be negative opinions expressed: "We cannot spend the money," "You cannot do it," "It is impossible," and so on.

Well, if you want to admit that you cannot, then stop this whole thing, pass no resolutions, and let things go as they will. I don't think, however, that that is the opinion of a wide-awake physician. If it is, then God help us. You have heard that there is health insurance in other countries. You can shout from the housetops that it is not a success there, but the public feels that it is. We are trying to offer something that we know is better for the public, but, like everything else, we have to sell it; it won't sell itself.

I know that the companies up to date, the Community Medical Care Plan or the Medical Expense Fund, have not made the howling success that we hoped they would; but at least let us make an attempt to help them.

There is one part in this report that I don't entirely agree with, but I don't consider it important enough to make any serious objection to it. I refer to the part where it almost insists upon, but not quite, having a medical man for director of the proposed bureau. Personally, I would not be so highly in favor of a medical man, because a medical man who has not succeeded in making a living so that he will accept such a job, I would be a little afraid of; but we might be successful in getting a medical man.

I want a live wire whose livelihood will depend upon trying to make this a success, who will feel that if he cannot do the job right he will lose his job.

It may cost us \$10,000, \$15,000, \$25,000, or even \$50,000, true; and if we do not succeed, then at least we have tried. Let us try.

DR. ARTHUR S. BROGA, *Madison*: In these days when you pay \$2.50 for a haircut, you can throw in \$100 for a lengthy study to be made on this proposition.

However, give us a good sound medical man to head it. If the miners can raise up a man like John L. Lewis, we ought to be able to raise up a good insurance man, who is also a good doctor, and who can tell us what to do along these insurance lines. I am all in favor of going ahead with this plan instead of waiting until the rest of my hair is gone and then bemoaning, in 1952, that we didn't go ahead and do something before we have things thrust upon

us that we don't want and which will do neither us nor the public any good. Let us go ahead with it, and at least make a try.

DR. MASTERSON: I would like to get something clear on the record first before the presiding officer puts the question. Dr. D'Angelo stated that in his opinion the creation of this bureau was not mandatory but was at the discretion of the Council. Our resolution says that the committee concurs in the recommendation of the Planning Committee for the establishment of a bureau. Is that an order or is it discretionary?

CHORUS: An order.

DR. MASTERSON: That is how I would interpret it. How would you?

VICE-SPEAKER HALE: I think that it is mandatory.

DR. MASTERSON: It is mandatory. That is all I wanted to bring out.

VICE-SPEAKER HALE: Are you ready for the question? You are voting on the recommendation of the Reference Committee approving the Planning Committee for Medical Policies' proposal to set up a Bureau of Medical Care Insurance.

. . . . The question was called for, and the motion was put to a vote, and was carried. . . . (Applause)

VICE-SPEAKER HALE: There is one more action that is necessary. The Reference Committee recommends the continuation of the Planning Committee for Medical Policies on the same basis as last year.

. . . . The motion was made by several, seconded, and as there was no discussion, was put to a vote, and was unanimously carried. . . .

DR. MASTERSON: I now move you the adoption of the report of the Reference Committee as a whole.

. . . . The motion was seconded, and as there was no discussion, it was put to a vote, and was carried. . . .

SPEAKER BAUER: I will declare a three-minute recess so you can stretch.

(There was a three-minute recess at this point.)

SPEAKER BAUER: The House will be in order.

#### Section 51. (See 39, 50)

#### Further Report of Reference Committee on Report of Council—Part VII: Nonprofit Medical Expense Insurance

SPEAKER BAUER: The Chairman recognizes Dr. Gartner, Chairman of the Reference Committee on Report of the Council, Part VII, Nonprofit Medical Expense Insurance. He has a report, which was postponed until the completion of the Planning Committee's report.

DR. A. A. GARTNER, *Erie*: Mr. Speaker, inasmuch as the House has adopted the resolution recommending the appointment of a full-time Director for Medical Expense Insurance, no action is necessary on the recommendation of our Committee which pertains to this matter. I, therefore, move that the report of our Reference Committee be accepted as a whole.

. . . . The motion was seconded, and as there was no discussion, it was put to a vote, and was unanimously carried. . . .

SPEAKER BAUER: Thank you, Dr. Gartner!

#### Section 52. (See 7)

#### Report of Reference Committee on Report and Supplementary Report of the Council—Part IV: Public Health Activities

DR. WALTER G. HAYWARD, *Chautauqua*: Your Reference Committee on Report of the Council, Part IV, Public Health Activities, has carefully con-

... report with complete wishes to commend the their diligent work and clear and painstaking reports.

We note with satisfaction that the New York State Council on Social Hygiene has advised the Council of their Sub-committee on Exchange Banks, and that they intend to submit to the 1945 New York State Legislature to the end that legislation may be enacted that will supplement, rather than supplant, existing facilities.

This report is signed by Edwin A. Griffin, Harry I. Johnston, Albert A. Cinelli, Leo P. Larkin, and Walter G. Hayward, Chairman, and I move the adoption of the report as a whole.

**SPEAKER BAUER:** This report pertains to public health activities, and is informative. Chiefly it covers 4-H Clubs and youth health activities, venereal and chest diseases, dental health, war

activities and for their own... The motion was seconded, and as there was no discussion, it was put to a vote, and was unanimously carried. ....

# Section 53

## Report of Reference Committee on Report of Board of Trustees

We note that many conditions, such as increased social problems, international money values and the possibility of advancing inflation, the pressing war expenditures, and the many and devious forms of taxation have given the Board of Trustees much con-

asset. The Trustees also state that the financial condition is sound, and this condition is due to:

1. Appreciation in value of the investment fund
2. The financial asset of the JOURNAL this year for the first time.
3. Income from investments.
4. Omission of publishing a Directory, saving the net cost, which was \$22,000; and
5. Last, but not by any means least, the conservative administration of the income of the Society.

We note that the financial condition of the Society would entail an amendment in the State Society Bylaws. The Board of Trustees states also that the financial soundness of the Society is largely due to careful management of the financial affairs of our Society by the Treasurer. This has been accomplished without curtailing the essential activities of the

ing, and because it would relieve the Board of

Trustees from functioning in a field for which they are not especially trained, and also because the decisions of the Board of Trustees would be easier and fewer, the recommendation of the Board of Trustees

nendation.

**SPEAKER BAUER:** You have before you the motion of the Reference Committee which carries with it the approval of the recommendation of the Board of Trustees that the Society's investments be placed in the hands of a trust company. Is there any discussion on it?

**DR. JOHN J. MASTERSON, Kings:** What would that cost us?

**DR. DI NATALE:** Nothing. .... The questi ..... tion was put to a vote, ..... o ex-

**DR. DI NATALE:** ... express its appreciation to the Board of Trustees for their watchfulness over the funds of our Society. May the Board of Trustees always be on the alert to protect the interests of the members of this Society.

I move the adoption of the report of the Reference Committee, consisting of Peter J. Di Natale, Chairman, Charles A. Anderson, Archibald K. Benedict, Alfred H. Noehren, and Ada Chree Reid, as a whole.

.... The motion was seconded, and as there was no discussion, it was put to a vote, and was unanimously carried. ....

# Section 54. (See 20)

## Report of Reference Committee on New Business A—Special Membership for Interns and Residents

**DR. JOHN D. CARROLL, Rensselaer:** The following resolution was presented by Dr. LeWin, of Erie County:

"WHEREAS, it would be in the interests of the younger men to join the State Society; therefore be it

"Resolved, that interns and residents in hospitals be permitted to join the organization at a reduced fee."

be ... Society would entail an amendment in the State Society Bylaws.

We recommend the disapproval of this resolution, and I so move.

.... The motion was seconded. .... **SPEAKER BAUER:** It has been moved that the resolution be disapproved and that the county societies take action to give such men local privileges. Is there any discussion on the motion, which carries with it the disapproval of the resolution?

**DR. JOHN J. MASTERSON, Kings:** For the information of the delegates, we have intern and student members in Kings County, and have had them for many, many years.

**SPEAKER BAUER:** We have the same thing in Nassau County.

DR. JACOB WERNE, *Queens*: And the same thing is true in Queens.

.... The question was called for, and the motion was put to a vote, and was carried. ....

SPEAKER BAUER: The resolution is, therefore, lost.

#### Section 55. (See 24)

#### Report of Reference Committee on New Business A—Establishment of Committee on Health Education in Each County Society

DR. JOHN D. CARROLL, *Rensselaer*: The following resolution was introduced by Dr. B. M. Bernstein, of Kings County, concerning the establishment of a Committee on Health Education in each county society:

"WHEREAS, the education of the public in health matters is of the utmost concern to the organized medical profession; and

"WHEREAS, the means and methods to be pursued in carrying on the education of the public ought to be and remain in the control of the county and state societies; therefore be it

"Resolved, that the Medical Society of the State of New York urge each county society to establish a Committee on Health Education either as a separate committee or as a subcommittee of the Committee on Public Health, in order to effectively carry on this very important adjunct of medical practice."

Your Committee approves the above resolution, and I move for its adoption.

.... The motion was seconded, and as there was no discussion, it was put to a vote, and was unanimously carried. ....

#### Section 56. (See 32)

#### Report of Reference Committee on New Business A—Approving Action of American Medical Association on Noninclusion of Medical Service in Hospital Insurance Plans

DR. JOHN D. CARROLL, *Rensselaer*: The following resolution was presented by Dr. Stephen H. Curtis, for the Section on Pathology:

"WHEREAS, the Council of the Medical Society of the State of New York has affirmed the position of the American Medical Association in opposing the inclusion of pathology, radiology, anesthesia, physical therapy, or any other form of the practice of medicine in a voluntary hospital or Blue Cross plan; and

"WHEREAS, it is opposed to hospitals accepting contracts of this kind and proposes that these insurance contracts for medical services be cared for by the voluntary nonprofit medical care plan; be it

"Resolved, that this House of Delegates go on record as approving this action by the American Medical Association."

Your Committee approves this resolution, and I propose its adoption.

.... The motion was seconded. ....

SPEAKER BAUER: Gentlemen, you have just voted on the same thing in the Planning Committee's report, which covered almost the same language. Unless there is objection, I will rule it is not necessary to take any further action. The resolution has really been approved in substance in the Planning Committee's report.

.... There was no dissent expressed. ....

#### Section 57. (See 28)

#### Report of Reference Committee on New Business A—Proposed Amendment of Bylaws of the American Medical Association Relative to the Powers of the Board of Trustees

DR. JOHN D. CARROLL, *Rensselaer*: This resolution was submitted by Dr. C. James F. Parsons, of the Westchester County Medical Society, and concerns "Proposed Amendment of Bylaws of the A.M.A. Relative to the Powers of the Board of Trustees":

"WHEREAS, it was clearly the intent of the framers of the Constitution and Bylaws of the American Medical Association that the House of Delegates shall be the supreme authority for the determination of the Association's policies; and "WHEREAS, Section 1 of Chapter VI of the Bylaws of the American Medical Association provides in part as follows: 'All resolutions or recommendations of the House of Delegates pertaining to the expenditure of money must be approved by the Board of Trustees before the same shall become effective;' and

"WHEREAS, this blanket authority conferred upon the Board of Trustees of the American Medical Association may be, and has been used as, a veto power on the part of the Board of Trustees upon resolutions adopted by the House of Delegates expressing the clear will and mandate of the House; and

"WHEREAS, it is clearly not in the best interests of the profession nor in harmony with democratic procedure for the Board of Trustees, existing only as an agent of the House of Delegates, to have the power and authority to countermand the declared purposes of the House of Delegates through the withholding of necessary funds for the accomplishment of such purposes; therefore, be it

"Resolved, that the delegates of the Medical Society of the State of New York to the House of Delegates of the American Medical Association, be instructed to propose an amendment to the Bylaws of the American Medical Association at the 1944 next meeting of the House of Delegates of the American Medical Association, providing that the sentence in Section 1 of Chapter VI of the Bylaws of the A.M.A. reading 'All resolutions or recommendations of the House of Delegates pertaining to the expenditure of money must be approved by the Board of Trustees before the same shall become effective' shall be deleted and that the following sentences shall be substituted for the deleted sentence: 'It shall be the duty of the Board of Trustees to make effective in the shortest possible time the expressed purposes and mandates of the House of Delegates as embodied in its resolutions and formal recommendations. In case the Board of Trustees shall object to such a mandate, it shall report its reasons to the House of Delegates at the earliest opportunity. The action of the Board of Trustees may then be overridden by a vote of two-thirds of the Delegates present and voting.'"

Your Committee feels that this resolution would seriously impede the satisfactory budgetary duties of the Board of Trustees of the American Medical Association, which has functioned throughout the years with no specific instances of frictional appropriation of funds in relation to the organization as a whole; therefore, I recommend the disapproval of this resolution, and so move.

.... The motion was seconded. ....

**SPEAKER BAUER:** You have before you the report of the Reference Committee, which recommends disapproval of the resolution. If you vote "Aye," you disapprove of the resolution, if you vote "No," you approve of it. Is there any discussion on the motion?

**DR. C. JAMES F. PARSONS, Westchester:** I feel it would be wrong if the purpose of this resolution and the one that preceded it earlier, which you threw out with such a thump, were not explained.

Very briefly, I will give you a summary of the discussion that led up to this resolution. We have to face facts, and not misinterpret the purpose of it. In any meeting I have ever attended in a local society, or in this gathering, for that matter, where the board of trustees or its equivalent in the county society came under criticism, it was always interpreted on a personal basis rather than what this is a criticism of the political structure. Any person acquainted with the workings of the American Medical Association who criticizes the Board of Trustees on a personal basis is wasting his time because, as anybody knows, over a period of ten years there has been a 70 per cent turnover in the personnel, so, as I stated before, we can dismiss that without any further comment.

Why did the interest in the governmental structure of the American Medical Association in this connection come up? Let us judge it on the basis of facts which are uncontested. You know that in the last few years there has been a great departure from the American Medical Association, from the solidity and the cohesiveness of the American Medical Association, as illustrated by the California group, the Far-Western States group, the Lake County, Indiana, group. From the talk in the stockrooms in your county societies the objection is to the American Medical Association's political structure, and not to its personnel—I emphasize that again—and rather extravagant suggestions have been made as to how to correct them. Let me put this question, and in doing so I am reminded that I am summarizing the discussion that led up to these resolutions. If the American Medical Association were functioning as our parent body satisfactorily, would the splittings from the national organization take place? I think they would not.

We discussed for a long time whether it would be opportune, or a good time, or even good judgment to bring in those two resolutions. Finally we decided we would because there would be a purpose served by it.

the duties of the organization as they should have done, or at least so it is felt in some quarters. Therefore, it is up to all the component units, in the interest of unity, to study the problem of why the American Medical Association apparently has not fulfilled that which we wanted it to do.

We need only to refer to the fact that unity is strength. We need only to reiterate that at this time we need unity and strength in our organization more than at any time in the long history of the American Medical Association since it started in 1847. It has evolved and done a marvelous job, but times have changed, and we are faced with the problem—and this is not the first time it has come up, I learned in the Reference Committee today that the same subject was introduced, I believe, last year, and I can assure you that the subject involved in this resolution will come up again, not

necessarily from this source, but it will come up again, and we have to face the fact—that the American Medical Association is apparently not doing the national job as a great many of those 116,000 members of the American Medical Association would like it to do. So does it not seem reasonable that all the component organizations should study first of all why the American Medical Association has fallen down, if you grant it has?

These two resolutions that I introduced this morning were by way of emphasizing that the political structure of the American Medical Association needs the most profound study.

I may digress for a minute to give a personal opinion, and that is that I believe it is the duty of all of our publications, state and county bulletins, to keep before the membership a constant picture of the political structure of the American Medical Association and its performance, so that they will understand it fully and have the means wherewith to improve and correct what is wrong.

If you were to ask me what I consider—and what I consider personally is unimportant unless it stands on its own legs—the greatest weakness of the American Medical Association, I would say that the individual member has no sense of participation. After the House passes a resolution, it is put up to the Board of Trustees, who act strictly within their constitutional privilege, and you will admit that you will hear unofficially from many sources that their power of veto has been exercised again. This is not a criticism of the personnel, because they are chosen in the established way. They are men of integrity, and, furthermore, I want to emphasize that the turnover is 70 per cent, or has been in the period of about

has fallen down, and it is our duty to study the question and the matter of checks, and balances to bolster it up. If the Board of Trustees take upon themselves this absolute power of vetoing your mandates, it is only reasonable to consider the possibility of the Board of Trustees' sometimes being in error, though they intended well. Therefore, a system of checks and balances should be instituted so that it can be referred back again to the House, and so that the House, representing your 116,000 members, can have some power. That seems only reasonable. These are the points that were behind these resolutions.

**SPEAKER BAUER:** Is there any further discussion?

The question was called for, and the motion was put to a vote, and was carried.

**SPEAKER BAUER:** The recommendation of the Reference Committee is carried, and the resolutions are lost.

#### Section 58 (See 9)

#### Report of Reference Committee on the Report and Supplementary Report of the Council—Part X Medical Licensure

**DR. MAURICE J. DATTELBAUM, Kings:** Medical licensure statistics recently completed for the year 1943 for the State of New York are not encouraging.

than the graduates of approved schools in this country.

The two recommendations proposed to the House of Delegates of the Medical Society of the State of

New York, at Buffalo, in 1943—namely, to refuse in the future to admit to examination for licensure any graduate of a foreign medical school 25 or more per cent of whose graduates taking examinations during the past ten years have failed to pass, and also the recommendation to limit definitely to three in all the number of examinations that may be taken by any candidate for licensure to practice medicine—have not met the favor of the Board of Regents. This decision is, of course, a great disappointment to the Council and the Committee on Medical Licensure.

The Citizenship Bill was not introduced this year because the Legislature would not entertain any controversial issue. It will be introduced at the next session of the Legislature in January, 1945.

The work of the Committee on Medical Licensure, we feel, should be approved in all its details and their suggestions should be heartily supported.

I move that the report of the Reference Committee, consisting of Maurice J. Dattelbaum, Chairman, Fenwick Beekman, Edgar O. Boggs, Walter T. Heldmann, and William A. Peart, be approved.

... The motion was seconded, and as there was no discussion, it was put to a vote, and was unanimously carried. ....

#### Section 59. (See 10-11)

#### Report of Reference Committee on the Report and Supplementary Report of the Council—Part XII: War Participation and General Matters

DR. DAN MELLEN, *Oneida*: There has been much work carried on, mostly by the Business Manager's Office, relative to obtaining physicians for induction throughout the State. There have been 10,000 physicians who have gone into the service from New York State. In the future they will be from the more recent graduates. It is suggested that the county societies make plans for re-establishing discharged physicians in their former practices, and to give physicians who have not previously been in practice necessary postgraduate work, and placing them in areas where they are most needed. The latter will call for the cooperation of the State Medical Society and the American Medical Association's Planning Committee.

It is recommended that the War Participation Committee be designated as the coordinating agency in this program.

An effort was made to find out how many alien physicians would be willing to return to their former homes in connection with the repatriation program. No accurate list of these men is available. We understand there are 3,650 of these men licensed in the State of New York and probably an equal number unlicensed. We suggest that the Committee continue their work by questionnaire and information from the Educational Department.

The Committee approves the nominations of the Council to the Committee on Grievances of the State Department of Education and to the Nurses Advisory Council of the Department of Education; also the nominations of the directors of the Physicians' Home—all as published on page 773 of the Report of the Council.

Concerning the Committee on Office Administration and Policies, this special committee has continued with the same personnel. The main work of this committee has concerned clerical salary adjustments.

We are familiar with problems facing the

Committee on personnel policies, and are confident they are using their best judgment in meeting them.

*Effects of Redistricting.*—As a result of these studies the Council went on record to the effect that it is of the opinion, based on legal interpretation, that the 1944 House of Delegates will assemble on the old basis of representation.

*Selection of Additional Delegate to the 1944 House of Delegates of the American Medical Association: Dr. William Hale.*—Dr. William Hale, who was highest in vote of the alternates, becomes the tenth delegate. This is provided for in Chapter 4, Section 6, of the Bylaws.

The Council has received and placed on file the following letter from Dr. Mabel E. Gardner, of the American Medical Women's Association, Inc.:

Dr. Peter Irving

Medical Society of the State of New York

Dear Sir:

At the Board Meeting of the American Medical Women's Association held in Chicago, June 5-6, 1943, great satisfaction was expressed that commissions and equal recognition of women in the armed forces has finally become an accomplished fact, thus removing the obstacle in the way of women physicians performing the highest patriotic service in their power in this crisis.

This Association, by unanimous vote, authorized me, as the secretary at that time, to express to you our appreciation for the unanimous support given by the House of Delegates of the Medical Society of the State of New York, not once but several times, and for the great privilege of being allowed to present our case in a series of letters published in the *State Journal*.

It gives me pleasure to thank you, in behalf of the Association, for this support of our cause.

Yours sincerely,

MABEL E. GARDNER, M.D.

The Council recommends payment of the following bills which were not turned in until after the expiration of the statutory thirty days and possible extension for ninety days more: bill from Dr. J. G. Fred Hiss, in his capacity as a member of a Subcommittee of the Council Committee on Public Health and Education, as a member of the Committee on Convention for the 1943 Annual Meeting, as a lecturer in the Postgraduate Courses and at the Annual Secretaries' Conference, bills for travel expenses and miscellaneous covering the period from July, 1942, through the Annual Meeting in May, 1943, totaling \$198.50; bill from Dr. Emily D. Baringer covering railroad fare to Atlantic City to attend the American Medical Association House of Delegates as a New York State Delegate, June, 1942, in the amount of \$9.00.

The Reference Committee approves action of the Council in remitting dues and State assessments of men in service, and also approves the action of the Council in recommending that county societies collaborate with nursing representatives of the Procurement and Assignment Committee of the New York State War Council for Nurses.

The Reference Committee approves the recommendation of the Special Committee of Office Administration and Policies that they be continued and that the personnel consist of the General Manager, the business manager of the *JOURNAL* and *Directory*, the Literary Editor, the Treasurer, and one member of the Board of Trustees, to be appointed by the President of the Society after consultation with the Chairman of the Board of Trustees.

I move the adoption of the Reference Committee's report, which is signed by Jacob Werne,

Burdge P MacLean, Stephen A Curtis, William C Meagher, and Dan Mellen, *Chairman*

**SILAS BAUER** Before we take up the adoption of the report as a whole there are three recommendations which we will take action on individually.

The first was the recommendation that the War Participation Committee be designated as the coordinating agency in returning physicians discharged from the armed forces back into practice. Is there any objection to the adoption of that recommendation?

There was none expressed  
**SPEAKER BAUER** Hearing no objection, it is carried

The second is one approving the belated bills which were submitted. As you know, bills are supposed to be submitted in thirty days, the Trustees can extend the time ninety additional days, beyond that only the House of Delegates can approve these bills. These bills have been submitted to the Reference Committee and itemized. Is there any objection to approving these belated bills for payment?

There was none expressed  
**SPEAKER BAUER** Hearing no objection, they are

was to continue the  
ation as outlined by  
the C Committee Is  
there a

**SPEAKER BAUER** If not, then all those in favor of the adoption of the report as a whole will say "Aye", those opposed, "No". The "Ayes" have it, and the report is adopted.  
Thank you, Dr. Mellen!

**Section 60 (See 13, 76)**

**Reference Committee on Constitution and Bylaws Amendments**

**DR. FREDERIC W. HOLCOMB, Ulster** In regard to the Proposed Amendment to the Bylaws, Chapter II Section 1, which is as follows:

"WHEREAS, the recently enacted reapportionment bill is based upon the population ratio and will thereby cause the House of Delegates of the State of New York

"Resolved, that the number of delegates from any component medical society be not reduced from their present number unless there has been a material reduction of the number of physicians in the area of any county medical society,"

your Reference Committee disapproves this proposed amendment for the following reason: the wording of this amendment is indefinite as to this portion "unless there has been a material reduction of the number of physicians in the area of any County Medical Society." No definition of the word "material" is given.

I move the adoption of this portion of the Report.  
The motion was seconded.

**SPEAKER BAUER** You have before you the recommendation of the Reference Committee that the proposed amendment be disapproved. Is there any discussion?

**DR. ALFRED M. HELLMAN, New York** There is such a small group present now to consider such an important matter that I should like to move that

we table or rather postpone action on this until tomorrow morning.

**SPEAKER BAUER** It has been moved that consideration of amendments to the constitution—I take it?—

**DR. HELLMAN** Yes.

**SPEAKER BAUER (continuing)** And not just this one?

Be postponed until  
a larger group

The motion was seconded, and as the Chairman was in doubt as to the result of a *via voce* vote, there was a standing vote, and the motion was declared carried by a vote of 52 in favor and 24 against.

**SPEAKER BAUER** You will have to come back, Dr. Holcomb, tomorrow.

"WHEREAS, there is an Insurance Committee of the Medical Society of the State of New York, and

"WHEREAS, one of the functions of this Committee is to supervise the Group Plan of Malpractice Insurance in order to provide for the membership protection in a reliable and sound manner, and  
as he has failed to  
as he evaded its re-  
of its function to  
and  
company other than

"WHEREAS, this condition has disrupted the

"Resolved, that the Bronx County Medical Society instructs its delegates to the State Society Convention to bring this matter before the House of Delegates at its 1944 meeting, and be it further

"Resolved that the present leading competitor

in  
her  
of  
pa

"Resolved, that the Insurance Committee of the State Society be directed to meet with other active competitors in malpractice insurance and submit regular reports on these meetings, and be it further

"Resolved, that copies of these resolutions be sent to the county medical societies throughout the State immediately."

**SPEAKER BAUER** That resolution is referred to the Reference Committee on Report of the Council, Part XI, of which Dr. Krakow is Chairman, since it

is very closely allied to the Report of the Council Committee on Malpractice Defense and Insurance.

*Section 62. (See 79)*

**Minimum Medical Fee Schedule of Workmen's Compensation Law**

DR. ABRAHAM KOPLOWITZ, *Kings*: I have two short resolutions, the first of which is:

"WHEREAS, the minimum medical fee schedule of the Workmen's Compensation Law was established by the Industrial Commissioner of the State of New York during normal times; and

"WHEREAS, on and after May 15, 1942, the hospitals in the State of New York were granted an increase in fees by the Industrial Commissioner following a conference and agreement by the representatives of the Compensation Insurance Carriers and the Hospital Association of New York State; and

"WHEREAS, the cost of living has increased within the past few years; therefore, be it

*Resolved*, that the Medical Society of the State of New York take such appropriate action as is necessary with the Industrial Commissioner of the State of New York and the representatives of the Compensation Insurance Carriers that an increase be granted to the medical profession for fees in the present 'Minimum Medical Fee Schedule.'"

Originally there was a percentage mentioned, but it was felt that perhaps that should be left open.

SPEAKER BAUER: That resolution is referred to the Reference Committee on New Business A, of which Dr. Carroll is the Chairman.

*Section 63. (See 83)*

**Workmen's Compensation—Deduction from Bills**

DR. ABRAHAM KOPLOWITZ, *Kings*: This is the second resolution I wish to introduce:

"WHEREAS, the practice of deducting 5 per cent from compensation bills which are paid within thirty days violates all business principles; and

"WHEREAS, the payment of bills is a purely business procedure; and

"WHEREAS, the usual business practice is the deduction of 2 per cent for the payment of bills within a stipulated reasonable period of time; therefore be it

*Resolved*, that the Medical Society of the State of New York be requested to arrange with the Industrial Commissioner of the State of New York that no deduction be made in the payment of bills for workmen's compensation cases."

SPEAKER BAUER: That is referred to the Reference Committee on New Business B, of which Dr. Eggston is the Chairman.

*Section 64. (See 40, 87)*

**Maternity and Infant Care Program**

DR. CHARLES GULLO, *Livingston*: I wish to present the following resolution having to do with the E.M.I.C. Program:

"WHEREAS, the present Federal Emergency Maternity and Infant Care Program of the Children's Bureau is intolerable, as it violates the physician-and-patient relationship; therefore be it

*Resolved*, that the Medical Society of the State of New York recommend to the American Medical Association through its Delegates at the next meeting of the American Medical Association that

it request the government or the Children's Bureau at Washington to alter the provision of the law or rule governing fees for maternity and infant care to provide that such money be paid directly to the patient as a medical allotment."

SPEAKER BAUER: I believe a similar resolution was acted on in a Reference Committee report.

CHORUS: It was postponed.

SPEAKER BAUER: That is right. It was Dr. Donovan's committee. We will refer this resolution to that Reference Committee, of which Dr. Donovan is Chairman—Part II of the Report of the Council—so a report can be brought in on this at the same time.

*Section 65. (See 80)*

**Basic Science Law**

DR. H. G. KNICKERBOCKER, *Ontario*: This concerns the Basic Science Law:

"WHEREAS, experience has shown that existing laws in New York State have proved ineffective in preventing the growth of the illegal practice of medicine; and

"WHEREAS, it is in the interest of the public health that steps be taken now, directed towards the eventual elimination of illegal practitioners of the healing art, through the enactment of laws which would effectively raise the degree of education of such practitioners to such a level that they might justly become legal practitioners; be it

*Resolved*, that the House of Delegates of the Medical Society of the State of New York instruct its Legislative Committee that it use its influence to have introduced a bill, at the next session of the Legislature of the State of New York, providing for the enactment of legislation so as to provide in the Education Law of the State of New York adequate guards against and prevention of growth of said illegal practice, and that such proposed legislation be known and designated as the Basic Science Law, which shall provide as a prerequisite for license to practice any of the healing arts satisfactory study and examination in the basic sciences—namely, anatomy, physiology, physiologic chemistry, bacteriology, pathology, and hygiene."

SPEAKER BAUER: That is referred to the Reference Committee on New Business A, of which Dr. Carroll is the Chairman.

*Section 66. (See 84)*

**Publicity**

DR. H. J. KNICKERBOCKER, *Ontario*: This resolution concerns the subject of "Publicity":

"WHEREAS, the practice of medicine is now and in the future is likely to, in a greater degree, become a political football, to the detriment of the profession as a whole; and

"WHEREAS, no coordinated, uniform policy involving active participation of the county societies, to the limit of their abilities to reach the public, within their individual areas, has been developed; and

"WHEREAS, the individual voter is the final deciding factor and should be able to cast his vote with a reasonable degree of intelligence based on all information available; therefore be it

*Resolved*, that a program aimed at reaching the public individually, in so far as possible, be instituted; and furthermore be it

*Resolved*, that all publicity, literature and

otherwise, originate with the State Society, be approved from the legal standpoint by the Legal Counsel and the Council before being sent to the constituent county societies for distribution and/or publication; and be it still further

"Resolved, that the responsibility for effective publication and/or distribution within its jurisdiction or the same shall be the duty and responsibility of each county society; and be it still further

"Resolved, that all expense incident to obtaining effective publicity of such programs as shall be initiated be paid the State Society; and be it still further

"Resolved, that the Council shall make such rules and regulations relative to the part county societies shall play in the accomplishment of the program."

SPEAKER BAUER: That is referred to the Reference Committee on New Business C, of which Dr. Kenney is the Chairman.

#### Section 67. (See 89)

#### A Plan for Medical Care

DR. SCOTT LORD SMITH, Dutchess: This resolution is presented in accordance with instructions from the Dutchess County Medical Society to its

voluntary insurance will be particularly difficult to carry out. We, therefore, introduce the resolution as we were directed, as follows:

"WHEREAS, the Medical Society of the County of Dutchess has approved in principle a plan to provide adequate medical care to that part of our population just above the line of indigency; and

"WHEREAS, the providing of medical care to this group is one of the vital problems of our day; and

"WHEREAS, the outline of this plan is attached to this resolution; be it

of Delegates refer to an appropriate

The outline of the plan referred to as being attached to the resolution is as follows:

#### "THE CALL

all far-sighted individuals strive.

"From the beginnings of recorded time each member of the medical profession has dealt with the health of a person or a community as an individual. Even when illness has been coupled with financial irresponsibility he has been able to do this to the general satisfaction of all, in accordance with the medical knowledge and the social consciousness of his period; but the time is now at hand, or very soon will be, when the doctor as an individual can no longer meet either standard. On the one hand, medical knowledge has become too vast for him to

"Will we surrender our position of leadership or will we collectively, as an organized group, fully aware of our responsibility for service and our capacity to give it, continue to provide this county with an ever improving grade of medical care?"

"The task of formulating such a plan has been delegated to us. It is with full awareness of the enormity of the problem, and humble appreciation of the frailties of found belief that only medical profession can medical service, that the following outline is submitted.

"Foreword.—Medical care is provided to the American people in four groups:

A. To those whose financial resources are always adequate to pay for such care.

B. Those who budget with voluntary hospital and indemnity insurance.

C. Those who cannot or will not provide insurance and therefore default on or are crushed by the financial load of illness.

"Category B is now very small but susceptible to enormous increase through education and favorable legislation. It is the rational, independent American way of making provision. All increases in category B will correspondingly decrease category C.

"D. Those who are wards of various welfare agencies, public or private.

"The first, second, and fourth groups are now taken care of by the high standards of American medical care. Group 3 provides the problem—i.e., to furnish high standard medical care to that part of our people above the level of indigency and below that of financial independence, without impoverishing the taxpayer. As in the first, second, and fourth groups the doctor sets the standard for medical care, so in the complex administration of the third group, trained and experienced medical men must be in control at the key points, if we are to obtain the desired result. Such points are the guiding body at the top of the plan and those giving actual medical care in the field. Between these two groups a trained business administration is imperative. To give the guiding and the professional care groups adequate authority is the problem which we believe best solved by this plan.

"Preamble.—A plan to afford adequate, high-standard, medical care in hospitals, at home, and in doctors' offices, to can people above the not or do not provide

it out.

1. It shall elect a chairman and one or more vice-chairmen from among its members.

2. Adopt rules and regulations for governing its debates.

3. Appoint appropriate committees and divide its work among them.

4. Arrange regional meetings as the need appears.

"The delegate from each state shall be a graduate in medicine and licensed to practice medicine in his state and be in good standing in his state medical society. He must be duly elected at a meeting of the House of Delegates of the medical society of the state he represents. Unless otherwise determined, his salary shall be a basic \$10,000 a year and expenses approved by the House of Delegates, and a sliding scale increase based on the population of the state in which he serves, and to be determined by the governing assembly. He shall serve a term of six years and be eligible for re-election except that at the election for the first Assembly one-third of the states (territories and the District of Columbia) determined by lot shall elect for two years, one-third for four years, and one-third for six years. These vacancies shall be filled at the end of their respective terms. Each delegate, in addition to his duties in the Assembly and on its committees, shall serve as an executive officer of his own state, reporting to the House of Delegates of his medical society. States of over 500,000 population may elect, in the same manner, deputies for each additional major fraction of a million population, each deputy to serve under the direction of his chief, in arbitrarily designated districts and possess all of his chief's duties and responsibilities except that of attending meetings of the Governing Assembly. His term of office shall be six years, and his salary a basic \$7,500 per year and expenses duly approved by the State House of Delegates.

"The House of Delegates may revoke the appointment of its representatives or his deputy on proof of unfitness to hold the office, and shall make interval appointments to fill the vacancies. The interim governing body of the state medical society may act for the House of Delegates when necessary between the meetings of that body. Any action so taken shall be subject to ratification at the next meeting of the House of Delegates.

"B. The Surgeon General of the Public Health Service or a deputy of his assigned to the position shall serve as a national executive officer of the Governing Assembly and make available to the Assembly the Public Health Services throughout the United States and its possessions.

"C. Such accounting and disbursing departments as may be necessary for the keeping of records and payment of monies for the Governing Assembly to the various states and counties.

"D. An organization in each county or district or combination of such paralleling the medical society organization, to determine in the case of each applicant:

1. His eligibility for such service.
2. The character and extent of the services necessary.
3. The county or district may elect either one of two methods:

(a) The county medical society may assume the responsibility and elect a committee of at least three of its members who shall meet once a month and review the bills submitted by doctors and hospitals for medical care and revise such bills as are not in accordance with the regulations.

(b) When no such action is taken by the Medical Society of a county the County Health Department or State Health Department District Office may review and revise such bills once a month.

"The decision of either the committee or the Health Department shall be final unless appealed to the State Executive Officer and reversed by him.

"Any doctor licensed to practice in the county who cares to work under the regulations set up by this act, and any hospital so agreeing shall be eligible to payment for services rendered to clients included in the third group of medical care as described above at the same rates and under the same regulations and for the same hospital accommodations allowed for Workmen's Compensation cases in the county in question.

"Obstetrical Cases.—(Details to be determined.)

"Tonsillectomies and Other Conditions Not Provided for Under Workmen's Compensation Rules.—(Details to be determined.)

"Doctors or hospitals working under this plan shall abide by the established fee schedule.

"When the county medical society administers the plan each doctor serving on its committee shall be paid by the county a fee of \$10 for each meeting fully attended by him.

"In cities and counties of over 100,000 population the county medical society may set up additional committees to review doctors' and hospital bills, dividing the districts as may be most convenient and electing to the committees doctors practicing therein.

"Financing.—The funds for financing this plan shall be allocated from those accruing to Social Security as provided by Congress. They shall be distributed to each county on the basis of estimated need and supplemented as further needs arise. They shall be in the charge of the County Governing Body (Board of Supervisors, etc.) and disbursed by the County Treasurer according to the regulations, to doctors and hospitals presenting bills for services rendered to clients who are certified by either of the plans set forth above.

"Recommended supplemental legislation referred to in the Foreword as designed to increase the membership of category B—i.e., those carrying voluntary health insurance—and correspondingly shrink category C:

1. Amendment to the national and state income tax laws to make all payments for medical, indemnity, or hospitalization insurance deductible in the full amount carried by the insured, whether such insurance be carried in a nonprofit association or a commercial insurance company.

2. Amendment of the National Security Act to permit the remission of one-half the Social Security payments each year up to the amount of premium paid for the year by a person insured for medical, indemnity, or hospitalization, whether such insurance be carried in a nonprofit association or a commercial insurance company."

SPEAKER BAUER: That is referred to the Reference Committee on New Business B, of which Dr. Eggston is the Chairman.

Are there any further resolutions?

Section 68. (See 85)

Change in Workmen's Compensation Law

DR. THOMAS M. D'ANGELO, Queens: I wish to introduce the following resolution:

"WHEREAS, at the recent session of the Legislature of this State, the Workmen's Compensation Act was amended in such a manner as to divide

the State of New York in this matter into two distinct portions, (1) the counties of New York, Kings, Bronx and Queens, and (2) the remainder of the State; and

"WHEREAS, this change removes from the four metropolitan counties the power to rate physicians for compensation practice, approve and license compensation clinics, arbitrate disputed medical bills, and investigate and try physicians for certain violations of the compensation law; be it, therefore,

"Resolved, that the Medical Society of the State of New York petition the next Legislature, and have legislation introduced to return to the

four county medical societies those powers that were abrogated by the recent change in the Compensation Law."

SPEAKER BAUER: That is referred to the Reference Committee on New Business C, of which Dr. Kenney is the Chairman.

Are there any further resolutions?

(There was no response.)

SPEAKER BAUER: We will recess until 9:00 o'clock tomorrow morning. Please be prompt because we still have a terrific amount of work to be done, and some of the issues still to come up are somewhat controversial, so they will take time.

.... The session recessed at 6:45 p.m. ....

## Morning Session

Tuesday, May 9, 1941

A.M.

... will be in order.

... present?

M. ... ASSISTANT SECRETARY POBYN: Yes, obviously. Sixty constitutes a quorum, and many more than sixty are present.

### Section 69

#### Report of Reference Committee on Report of the Council—Part VI: Public Relations and Economics

DR. DAVID W. BEARD, *Scholarie*: The work of this Committee, consisting of Herbert H. Bauckus, M.D., Buffalo, Harry Aranow, M.D., Bronx, and Charles M. Allaben, M.D., Binghamton, has been enormous and has involved a great number of meetings and consultations. The nature of their endeavors has been both coordinating and assisting other groups. They were, however, not in a position to make specific recommendations, but summarized and elucidated the results of their deliberations. In view of the fact that so many economic problems that confront the Medical Society of the State of New York have been delegated for study by special and standing committees, such as nonprofit medical expense insurance, workmen's compensation, public health and education, and many others, we feel it would be only a duplication of effort for us to comment on all of these various subjects.

The report calls attention to the importance of advising the people of the standards and aims of the practitioners of medicine, that we are fighting a world war abroad, and at the same time training another group to carry on, as well as caring for the people left at home and keeping them in the best physical condition in our history.

The report further calls attention to the activities of the new Planning ... which was authorized the House of Delegates

study of the report on the ... The committee met on several occasions with the Public Health and Education Committee in accordance with the wishes of the Chairman of that Committee, Dr. O. W. H. Mitchell. It studied closely the Emergency Maternity and Infant Care Program of the Federal government and the New York State Department of Health.

The report calls attention to the importance of the Workmen's Compensation Bureau, the Council

contact with the New York State Council for War Service, and has continued as a member of the Atlantic Seaboard Agricultural Workers' Health

time was spent by the ... newer developments for ... including the Beveridge Plan of England and the provisional Health Insurance Act of Canada and the developments in Wagner-

under the ... lph T. B. Todd, M.D., Tarrytown, Carleton E. Wertz, M.D., Buffalo, and Charles F. Rourke, Schenectady. This report calls attention to the fact that owing to the ... many of the problems ... been relieved. However, ... lose touch with the Department of ... this period and discussed the question of payment of medical fees for services rendered old assistance clients. Some of the restrictions formerly placed on participating practitioners in the care of welfare patients have been removed. The Committee was advised that the removal of these restrictions was made possible

the great need of committees on economics of the state and county societies to study carefully constitutions, bylaws, and contracts of all insurance plans submitted to them by insurance carriers, unions, or employer groups.

Your Reference Committee feels that the activities of the Committee on Public Health and Economics have been well carried out, and highly endorses and commends the accomplishments of the past year. It is the hope of the Reference Committee that the work of this Committee will be continued with the same high standards as in the past.

I move the adoption of this report, which is signed

by D. W. Beard, *Chairman*, G. S. Philbrick, Maurice C. O'Shea, Bernard S. Strait, and William Klein.

**SPEAKER BAUER:** You have before you the recommendation of the Reference Committee for the adoption of their report. It presents no controversial issues, discusses the work of the Council Committee during the past year, and recommends its continuation along the same lines.

.... The motion was seconded, and as there was no discussion, it was put to a vote, and was unanimously carried .....

#### Section 70

#### Report of Reference Committee on Report of Secretary, Treasurer, Censors, and District Branches

**Report of the Secretary.** DR. EDWARD P. FLOOD, *Bronx:* Your Reference Committee has only commendation to offer for the work done by the Secretary as evidenced in his report.

We note with satisfaction that the total membership has increased and that relatively few members have been dropped for nonpayment of dues. We wish to congratulate the twenty-four honor counties for having maintained their dues-paying membership 100 per cent.

In the conduct of the New York Office, we note with approval the employment of three additional members of the *JOURNAL* staff and agree that having our own advertising salesmen will eventually prove more satisfactory than the previous arrangement with the late Kent Lighty.

We note with pride the work of the War Participation Committee in cooperating with the Selective Service system. Recognition is taken of the added obligations of the Secretary's office, consequent upon the appointment of new committees and subcommittees without the addition of new employees. We accept the Secretary's recommendation that the legislative chairmen and the county secretaries have their fall meeting on the same day, in the same place. We are pleased that our Secretary enjoys the confidence of Governor Devey and has thus merited appointment on the Commission to Investigate the Department of Mental Hygiene in the State of New York.

We note with regret the passing of Miss Lily B. Baldwin, a faithful employee of the Society for thirty-seven years.

We concur in the Secretary's expression of gratitude for the loyal devotion of Miss Dougherty and the other members of the office staff to the interests of the Society.

Mr. Speaker, I move the adoption of the Reference Committee's report, covering the Report of the Secretary.

.... The motion was seconded, and as there was no discussion, it was put to a vote, and was unanimously carried .....

**Report of the Treasurer.** DR. FLOOD: Your Reference Committee on the Report of the Treasurer recommends hearty approval of the Report as a whole. We commend him for the efficient manner in which our financial affairs have been handled during the past year. We approve the disposition of the matter pending between the estate of the late Kent Lighty and the Society and we approve the present policy regarding solicitation of advertisements for the *JOURNAL*.

We recommend that the liquid cash assets of the Society, such as the various prize funds now on deposit at the Union Dime Savings Bank, be converted to United States War Securities, in the form

of coupon-bearing par value bonds, to such an extent as is practicable.

We view with some concern the mounting financial surplus of this Society, which surplus must eventually be spent or become endangered of future depletion through taxation or inflation.

We, therefore, recommend that our future expenditures for such projects as postgraduate medical education, especially of our demobilized members; the extension of nonprofit medical expense insurance on a state-wide basis; publicity and lay education in all matters relevant to our relationships to the public; and all other projects for the promotion of the public health and welfare be increased in proportion to our assets.

Mr. Speaker, I move the adoption of the Reference Committee's Report on the Report of the Treasurer.

.... The motion was seconded, and as there was no discussion, the motion was put to a vote, and was unanimously carried .....

**Report of the Board of Censors.** DR. FLOOD: The Reference Committee has not received a report of the Board of Censors' activities in the past year. However, we take this opportunity to reaffirm our belief in the integrity of the principles of professional conduct of the Medical Society of the State of New York and recognize that the enforcement of these principles is dependent upon a proper understanding of the rule of right action.

This rule of right action is defined by the Judicial Council of the American Medical Association in its report to the members of its House of Delegates published in the *Journal of the American Medical Association* on April 29, 1944, excerpts from which I take the privilege of quoting at this time:

"At various times, resolutions have been presented in the House of Delegates directing the Judicial Council or an appointed committee to rewrite or more precisely define our principles of medical ethics, giving illustrations of unethical action which would guide the ethical judgment of the membership.

"Such revision of the principles of medical ethics is not the answer to this problem. To illustrate or elucidate would only produce 'confusion worse confounded.' Rather let us firmly identify in our minds these dictionary definitions:

"(a) 'A law is a rule of action established by recognized authority to enforce justice and prescribe duty.'

"(b) 'A principle is (1) a general truth; (2) a settled law or rule of action, especially right action, consciously adopted.'

"(c) 'Ethics is the basic principle of rules of right action.'

"Law which is punitive in action deals only with a specific crime or misdemeanor and must be so particularly applied (witness the row upon row of tomes necessary to the lawyer's library) as to permit no loopholes for evasion. The American Medical Association has no laws to compel its membership to care for the sick or the public at large. That would be foreign to our conception of the principles of medical ethics, which reflect our pride in 'a rule of right action, consciously adopted.'

Mr. Speaker, I move the adoption of the Report of the Reference Committee on the Board of Censors.

.... The motion was seconded, and as there was

no discussion, it was put to a vote, and was unanimously carried.

**District Branches** Dr Flood Your Committee notes with much satisfaction that the various District Branch reports denote a large attendance with excellent scientific programs in which many of the individual members participated. War medicine with its various ramifications proved especially interesting.

Although the President of the State Medical Society, Dr McGoldrick, is a very busy man, he nevertheless took the necessary time to attend each meeting, and by his presence and by his addresses added greatly to the pleasure and interest of all who attended.

Mr Speaker, I move the acceptance of this report on the District Branches.

The motion was seconded, and as there was no discussion the motion was put to a vote, and was unanimously carried.

Dr Flood Mr Speaker I now move the acceptance of the complete report of the Reference Committee consisting of Edward P. Flood, Chairman, Madge C. L. McGinness, Reginald A. Higgins, W. Grant Cooper, and Theodore W. Neumann on the reports of the Secretary, Treasurer, Board of Censors, and District Branches.

The motion was seconded, and as there was no discussion, it was put to a vote, and was unanimously carried.

#### Section 71

##### Executive Session

**SPEAKER BAUER** Dr Brady of Erie County, in case of an executive session, you are designated as Sergeant-at-Arms. Dr Clemans of Fulton County, you are assistant to Dr Brady. Dr Buettner, of Onondaga County, you will also be an assistant to Dr Brady.

Dr Simpson are you ready to give your report?

Dr LEO F. SIMPSON Yes.

**SPEAKER BAUER** Dr Simpson's report pertains to Workmen's Compensation. In the opinion of the Chairman, it would be advisable if we went into executive session.

Dr JAMES F. ROONEY, Albany I so move.

Dr LOUIS A. VAN KLEECK, Nassau I second the motion.

**SPEAKER BAUER** It has been moved and seconded that we go into executive session. The Chairman will take it for granted that the Executive Officer, Dr Lawrence, the Director of the Bureau of Public Relations, Mr. Anderson, Mr. Martin, the Legal Counsel, Mr. Clearwater, the Attorney, Miss Dougherty, and of course our stenotypist, Mrs. Grimm will be permitted to remain during the executive session.

Do you wish to include any others?

Dr RALPH T. B. TODD Westchester I move we have the executive secretaries of the county societies.

**SPEAKER BAUER** Is there any objection to including the executive secretaries of the county societies? If not, the motion to go into executive session will except those gentlemen.

The question was called, and the motion was put to a vote, and was unanimously carried to go into executive session.

Dr JAMES F. ROONEY Albany I move we take a recess of two minutes until the room is reported clear of any but delegates.

The motion was seconded and as there was no discussion it was put to a vote, and the recess

was taken in order to clear the room of all but delegates and those named who were permitted to stay for the executive session.

**SPEAKER BAUER** It has been called to our attention that under the motion as worded alternate delegates would be excluded. Is there any objection to including them?

**CHORUS** No.

**SPEAKER BAUER** They will be permitted to remain during the executive session, with the others named.

Mr Sergeant at Arms, are you ready?

Dr JOHN C. BRADY, Erie The hall is cleared of all except the delegates and those named by you who are permitted to remain during the executive session.

**SPEAKER BAUER** Proceed Dr Simpson.

#### HOUSE GOES INTO EXECUTIVE SESSION

*In accordance with custom actions so taken at Executive Session are not published but recorded only in the official office copy of the Minutes of the House of Delegates.*

*However the House on motion duly seconded and carried, unanimously adopted with applause the following report, and directed that it be transmitted to the press and to the Governor.*

LOUIS H. BAUER, M.D., Speaker  
PETER IRVING, M.D., Secretary

#### Section 72 (Sec. 8)

**Report and Supplementary Report of the Reference Committee on Report and Supplementary Report of the Council—Part IX Workmen's Compensation**

Dr LEO F. SIMPSON, Monroe The report of the Council Committee on Workmen's Compensation is really a résumé, not only of the substantial contributions made by the present committee, but also of the work of this committee and the State Society Bureau during recent years.

A close study of this report to the Council reveals that its members possessed a very comprehensive knowledge of the Workmen's Compensation Law, knew well how the law functioned in reality and, in addition, had an acute awareness of how it should have been modified in order that it might more completely accomplish its objectives.

The outstanding work of a former committee of physicians, under the chairmanship of Dr Eugene Pool resulted in the amendments to Section 13 of the Workmen's Compensation Law in 1935. All of their recommendations unfortunately, were not enacted into law. Had their recommendations been fully enacted much of the bad odor liberated by the recent problems would never have been generated. What this committee of physicians did accomplish, however, was constructive, forward-looking, and of great value. The medical profession was given authority, great responsibility, and the unique power of self-discipline.

The magnificent response of the medical profession to the great obligations imposed upon it by the 1935 amendments is a matter of history. The compensation committees of the county societies have carefully and conscientiously discharged their duties—and your Reference Committee subscribes to a statement in the report which says, "We believe it is not too much to assert that no interested parties to the Workmen's Compensation Law, not even the Labor Department, have made

a greater contribution to the public welfare than the medical profession through its agencies."

It may be said also that all of the great work done by the various county societies has been but the lengthened shadow of the Workmen's Compensation Committee of the State Society and of its Bureau.

The prodigious amount of work done by this Council Committee is a monument of honor to the men who have made up the Committee and Bureau through the years.

They have been a continuous advisory committee to all county societies. They were also a public relations committee of the medical profession to the Department of Labor, the insurance carriers, the employers, and the working man.

It has been through the untiring efforts and specialized knowledge of the Committee and of the Bureau of Compensation that organized medicine, through its component societies, has functioned so well. The rating of thousands of physicians who wished to qualify under the provisions of the Law has been a task of great magnitude, and it is the opinion of your Committee that it has been done efficiently and conscientiously. The few complaints that were made by the physicians came from those who thought their ratings were not sufficiently high.

The Bureau, in addition, has ably fought for the legal and financial rights of the physicians under the Law as amended in 1935, against the innumerable assaults that were made upon these rights. Free choice became more than a legal fiction, at least in upstate New York. Fees were paid promptly, special services were more adequately rewarded, and the arbitration of disputed bills was efficiently handled. The medical profession of the State of New York owes a great debt to this Bureau.

Your Council Committee and Bureau have clearly recognized the evils that were inherent in some of the ambiguities and redundancies of the amendments of 1935, and have frequently sought by all means to obtain amendments to the Law, to clarify and simplify the statutes, so that they could be more effectively administered to the end that the medical profession could more effectively carry out its responsibilities. But to little or no avail.

On January 13, 1944, your Council Committee presented to the Council certain recommendations to be presented to the Moreland Act Commission which was then functioning. These recommendations were approved by the Council. More of this later.

After the writing of this report of the Council Committee, the Moreland Act Commission finished its investigations, made its report to the Governor, and suggested and had enacted into law many significant changes in the Law from the viewpoint of the medical profession.

One would imagine from the newspaper accounts of recent months that the main culprit under investigation by the Moreland Act Commission was the medical profession. It is a fact, however, that not only a portion of the medical profession but also a portion of the legal profession, some insurance carriers, some employers, the State Insurance Fund, licensed representatives of the workingman, and the administrators of the Department of Labor itself—all were excoriated in the report to the Governor, and many changes were made in the Law designed to correct not only evils that had arisen in medical administration but also to curb the very questionable activities in all other departments hav-

ing to do with the administration of the Compensation Law.

It may be, perhaps, that the newspapers considered the finding of medical scoundrels to be news—the inference being that the finding of all the other scoundrels in the administration of the law had no news value. (Laughter and applause)

The report of the Moreland Act Commission revealed two outstanding medical evils: one concerned the commercial laboratories, x-ray and others, supply houses for medical appliances, suppliers of oxygen, etc., and the nefarious financial relationship that existed between them and many physicians; second, the activities of many members of the medical profession were exposed, proving them to be without either honesty or professional honor. A few of the latter formed rings with lawyers and licensed labor representatives, aimed at perverting the very law itself, and depriving the workingman of his just rights. Fee-splitting, bribery, flourished on every side.

The Commission, in addition, placed the blame on the compensation boards, especially on four in Greater New York, and on your State Bureau for their inaction and neglect in curing these conditions.

Your Reference Committee feels that this accusation should not pass unchallenged.

First, as to the commercial laboratories: the proposal that the commercial laboratories be banned was made by the Pool Committee, and was included in the original draft of the bill that created the amendments of 1935. This was emasculated through the activities of certain commercial interests, and the way was left open for commercialism in compensation practice. Had the suggestion of the medical profession on this point been enacted into law, the problem of the commercial laboratory, with all of its inherent evils, would have ceased to exist in compensation law. It was, therefore, legal for them to function under the Law, as it was for a certain percentage of the medical profession who, by their general lack of morality, cast a sinister shadow over an honorable profession. We hold no brief for these men. We do not defend them. We do not apologize for them. We condemn them without reservation.

The criticism directed at the compensation boards of the county societies and of your State Bureau by the Moreland Act Commission for their inaction and laxity in curbing these nefarious gentlemen in our opinion is not fully justified, the more so when we see the same commission enact into law a procedure that would give the county society compensation boards a real power and procedure to deal with professional misconduct.

The enactment of this law at the request of the Moreland Act Commission is really an admission on the part of the Commission that the capacity and power of the compensation boards was entirely inadequate to cope with the situation.

Incidentally, it was not until May 4, 1943—eight years after the enactment of the amendments—that the county societies were informed that they were authorized to subpoena witnesses and render the oath to witnesses. We have in this belated interpretation by the Attorney General of the Civil Practice Act an opinion that it is inherent in the Law that the compensation boards of the medical societies have that power. This opinion now is even questioned by legal authorities. The opinion indicated, however, that such authority is not contained in Section 13-d of the Compensation Law it-

self. If the compensation boards had had that definite authority from 1936 on, there would have been no nose-thumbing at the compensation committees of the county societies and far less no e-holding when the probers went to work last year.

Previous to May, 1943, the boards believed they had no such power. Without that power any legal investigation committee is helpless. Without a subpoena a man could refuse to appear, and without an oath only his reputation as a liar would be at stake. The boards had no one to initiate charges,

all and  
all to

conduct so rampant around them would be an insult to their intelligence, that some of them failed to use all the little legal power they had is possible. Knowledge of a crime, and even of a criminal, is one thing, but the serious business of putting a permanent stop to the criminal is still another. To do that, one must have power, and the legal powers of the compensation boards in this serious matter were mythical.

To say that your Bureau and the compensation committees of the medical societies, especially those of Greater New York, were inactive or lax after they were assured of any legal power to try the offenders is—to put it very mildly—untrue. That there was apparent laxity and inaction previous to this was due to the facts contained in the following paragraph taken from the report of your Council Committee on Workmen's Compensation of January 6, 1944:

For many years we have been advised that we possessed no such power of subpoena. This is evidenced by numerous communications to the Industrial Commissioner and from him to us. Specifically, in the year 1937 the Director of Workmen's Compensation of the State Medical Society requested the then Commissioner to issue subpoenas and provide an officer to administer the oath when required or to have investigations made by the Industrial Council of the Department of Labor, which possesses such power. The Commissioner, accepting the general belief that the Medical Society did not possess the power to subpoena etc., agreed to have investigations by the Industrial Council, but such investigations were never held. Our own Counsel and others whom we consulted were of the opinion that unless a specific provision was included in the Workmen's Compensation Law (Section 13-d), we did not possess the powers to subpoena and administer the oath without which no successful investigations or trials could be held."

After the appointment of the Moreland Act Commission and the election of a new Attorney

Commission contained the names of over 1,300 physicians who were accused of unethical conduct. In all, the names of 3,000 were given out. These physicians were under the jurisdiction of the compensation boards of the counties of Bronx, New York, Kings, and Queens.

The names were released from time to time, the last not obtained until January, 1944. All of the physicians whose names appeared on the first lists were heard by the societies and either admitted or denied their guilt. For instance, in Kings County, of 1,110 physicians who were named by the Moreland Act Commission, 380 are in the Army and could not be heard, 400 have pleaded guilty, and the 160 who pleaded not guilty have been tried. Kings County has completed its work as of May 5.

(This investigation showed that of 1,140 men who were accused of unethical misconduct, the total take, as you may say, over a period of three or four years, was \$16,000, which would average about \$14 a man over two or three years, while the Moreland Act Commission accused and convicted one representative of labor who in one year had taken \$13,000.)

It was arranged that all who denied their guilt would have a final trial as soon as all the physicians named had an opportunity to be heard in a preliminary hearing. After a great many had been heard, the counsel of the New York County Society raised the question of the legality of the proceedings, unless charges were first preferred by the Industrial Commissioner, and it was not until April, 1944 that these formal charges were made by the Industrial Commissioner against all of the accused.

Up to the present time the various county society boards of the metropolitan area have heard one tax case.

All of this was done without undue delay, considering the legal questions raised by the counsel for the New York County Society and by others as to the authority of the medical societies to act.

The Department of Labor, as was their apparent right under the Law, held independent hearings to try certain accused physicians. When they revoked the license of one physician to practice under the Compensation Law, he carried it to the Supreme Court, which held that the Department of Labor had no such power.

The mistake, if there is action or the were lax or timid, once they were assured of any power, is absolutely untrue.

Your Reference Committee has also studied the steps taken by the Committee on Workmen's Compensation of the Medical Society of the State of New York concerning the Moreland Act Commission's investigations. This report is dated April 27, 1944.

It is a documented statement of the aid given by the State Society Committee by your Compensation Bureau, by the presidents of the five societies in the metropolitan area, by the chairmen of the compensation boards of these societies, to the members of the Moreland Act Commission—not only in the investigation, but also by their many and valuable recommendations for the improvement

vision in the State statutes to enable the State Society to exercise these powers. Finally, on May 3, 1943, the Attorney General gave the opinion that we have mentioned above. There is nothing in the Law which stated that the Compensation Board must initiate charges against a bureau or a physician. It states merely that it shall hear such charges, determine guilt or innocence, and report its findings to the Industrial Council. The first list of physicians given out by the Moreland Act

of the administration of the Compensation Law. Many of these recommendations are embodied in the new Law, and it is beyond the comprehension of your Reference Committee how this same commission could in any way censure these gentlemen.

We believe that the physicians composing the compensation boards of the county societies throughout the State—and, of course, that includes those of the Counties of Bronx, New York, Kings, and Queens—were in general conscientious, diligent, and trustworthy. Although the rest of the county societies retain their former status, with new powers under the Law, we feel that the substitution of a three-man medical practice committee for the boards of the above-mentioned societies in Greater New York is an affront to the honor and dignity of the medical profession, and that every honorable effort should be made to modify the new Law to the end that these boards be restored to their proper sphere.

Professional honor is a very personal matter with the men who composed these four boards, and it is our opinion that they should be permitted to function under the new powers granted by the Legislature. We also believe that it would make for better administration of the medical aspects of the Compensation Law.

Your Council Committee, as we have stated, made certain recommendations to the Moreland Act Commission, by the authority of the Council.

Your Reference Committee concurs in their validity and wisdom, and although the greater number of their recommendations were recently enacted into law, the few that have not been should be the subject of continued study by this Committee, and again advocated, if the operation of the newly amended Law would indicate their necessity.

The Moreland Act Commission has enacted into Law, which will become operative in June, 1944, many changes that your Reference Committee wishes to point out. Many of these changes were recommended by your Council Committee to them on January 13, 1944. The essential changes, having not been enacted at that time, obviously were not discussed in the report of the Council Committee, but your Reference Committee thought it incumbent upon it to bring matters up to date. They are as follows:

1. The Industrial Council now consists of nine members instead of fifteen. Three members will be physicians and are called the "medical appeal unit" of the Council. They shall consider all matters connected with the practice of medicine submitted to them by the Commissioner and the Industrial Board, and shall prescribe rules and regulations to govern the procedure of investigations and hearings by medical societies of charges against authorized physicians, laboratories, or bureaus.

2. The Compensation boards of the medical societies of the Counties of Bronx, New York, Kings, and Queens are abolished, and in their place is set up a single medical practice committee of three outstanding physicians. The compensation boards of the other county societies remain the same as before. The three-man medical practice committee of Greater New York will have the same power as other societies in authorizing physicians, laboratories, and bureaus. In addition, they will be the arbitration committee, and the hearing and investigating committee, of all charges against physicians, laboratories, or bureaus in that area.

3. The method of arbitrating disputed bills in

other sections of the State has been modified so that now the arbitration board shall consist of two members of the local county society, two from the State Society, and one appointed by the Commissioner.

4. Conviction of fee-splitting in all its forms is now penalized by loss of authorization to function under the Compensation Law, and is also a misdemeanor. In addition, conviction carries with it possible loss of license to practice medicine under the newly amended Education Law. Incidentally, any other person not a physician who attempts to aid a physician in splitting a fee is also guilty of a misdemeanor.

5. Under the new law, commercial x-ray laboratories are put out of business, and only a roentgenologist authorized by the compensation boards, or by the medical practice committee can practice as such under the Law.

6. The medical practice committee in New York City and the compensation boards elsewhere are now to have real power as well as legal assistance in hearing and investigating charges of misconduct against either physicians or licensed bureaus and laboratories.

7. All medical bureaus, laboratories, etc., henceforth must be licensed by the Commissioner, and the new changes in the Law make possible standards of efficiency and professional competency never possible under the old law. In addition, the power to discipline is now very definite.

8. It is now the law that any interference by any person with the selection by an injured employee of an authorized physician to treat him, and the improper influencing of or the attempt to influence the medical opinion of any physician who has treated or examined an injured employee shall be a misdemeanor. (That takes this common practice out of the realm of fun, and places it in a criminal category.)

9. When a claimant is to be examined by a physician employed by the Department of Labor, no physician employed by the employer, carrier, or employee shall be present at, or participate in any manner in, such examination.

10. No claim for medical or surgical treatment will be valid in the future unless within forty-eight hours the physician makes a report to the employer, and also directly to the Industrial Commissioner. Insurance carriers, also, when they have a claimant examined, must file a copy of the report directly with the Industrial Commissioner within ten days.

11. The new law also authorizes the industrial commissioner to employ physicians of outstanding qualifications as committees of expert consultants in such fields of medicine as he deems essential in order to ascertain the diagnosis, causal relationship, or adequacy of medical or surgical treatment in cases in which such matters are not readily determinable by the regularly employed medical examiner in the Workmen's Compensation division.

12. It is interesting to note that under the new law the Industrial Commissioner is made an absolute power. None of the recommendations made to him by a county society board, by the medical practice committee in New York City, by the medical appeal unit of the Industrial Council, are final, binding, and conclusive on him, as in the old law. They are now advisory only, and if he wishes to ignore them he may legally do so.

The new law will soon be effective, and should correct many evils. Whether all of its provisions

are wise can be determined only by experience in its operation. The significance of your Bureau will become apparent. The importance of its work in the past can be estimated only by one who has studied the importance of its manifold activities.

It is estimated that under this law in New York State \$20,000,000 is paid annually for the professional services of physicians. To strive on the one hand to protect the financial rights of the physicians and, at the same time, to insure that the quality of medical service delivered to the workingman is of the highest possible quality are among a few of its functions. Its other duties have been many, arduous, and exacting, and it is the opinion of your Reference Committee that they have all been discharged in a very adequate manner. It should have the enthusiastic and unwavering support of the medical profession. The Bureau of the Medical Society of the State and the personnel of the medical profession are partners in the great enterprise of rendering the highest type of medical care to the workingman, and the dignity and com-

We feel sure that your Council Committee and Bureau will ever bear in mind the obligation to use the full activities of the societies of the State, and Queens, and the new law, your Reference Committee has but one recommendation to make

It is one that we have obtained from a study of a contribution to this subject by a committee of the New York Academy of Medicine, slightly amended.

Our recommendation is this: That in so far as the medical aspects of the Workmen's Compensation Law are concerned, the Governor be petitioned to appoint each year a state-wide committee of physicians to review the situation, and to suggest such studies or changes as might be indicated in order that weaknesses of the law or of its administration

OF LEO I.  
John J.  
V. Strohm,

The motion was seconded by several. . . .  
SPEAKER BAUER: You have before you the motion of the Reference Committee on what the Chairman considers is a most comprehensive and very important subject. . . .  
The subject is of great importance and the committee has made a most commendable effort to bring out a most comprehensive and important subject. . . .

The question was called for, and the motion was put to a vote, and was unanimously adopted amid applause. . . .

DR. LAURENCE D. REDWAY, Westchester: May I request the privilege of this floor as an editor of the JOURNAL of this Society:

SPEAKER BAUER: You may.

DR. REDWAY: In justice to the many physicians who for so many years have labored to make the content of this report possible, and also in justice to the physicians of the State who have carried on the compensation work in this State so commendably, and also in justice to the enormous amount of work that this Reference Committee has put it on

this report, I request the privilege and the vote of this House for permission to publish this report in the JOURNAL of the State Society.

DR. JAMES F. ROONEY, Albany: I second that motion.

DR. REDWAY: In its entirety.

There being no discussion, the motion was put to a vote, and was unanimously carried. . . .

SPEAKER BAUER: You have the authority, Dr. Redway.

#### Section 73-74

(Sections 73 and 74 appear in the office copy of the Minutes only.—Secretary)

SPEAKER BAUER: The House will now rise from executive session, unless there is objection. I take it there is none. The Sergeant-at-Arms and his assistants are thanked, and the doors can now be opened.

#### Section 75. (Sec 4-5)

#### Report of Reference Committee on the Reports of the President and President-Elect

DR. W. GUERNSEY FLY, Jr., Queens: The admirable report of the President, Dr. Thomas A. McGoldrick, review of the past year. The summary is so concise, the conclusions expressed are so unquestionably representative of the viewpoint of the membership, that your Committee can but recommend the entire report to the careful perusal of every member.

We single out only a few items from the report for particular notice. Dr. McGoldrick points with pride to the fact that 10,000 doctors from New York State are in the armed forces, but he does not overlook the fact that with greatly depleted ranks and reduced facilities of all kinds, the medical men not in uniform have carried on, the health of the home front has been maintained, and the science of medicine has been advanced. He commends particularly the activities of the Council Committee on Public Health and Education.

In commenting on the Federal Emergency Maternity and Infant Care Program, the President well expresses the views of the Society in the following words:

"With the object of the Act, to provide maternity and infant care for the wives and babies of members of the armed forces in the four lower grades, let me express our complete accord. With such details as the interposition of a third party, . . . . . we are in complete agreement."

As an alternative to the undesirable features in national

E. M. I. C. . . . .  
lay and . . . . .  
sp . . . . .

is . . . . . brevity, . . . . .  
be . . . . .  
committees of the Society who have most distinguished themselves in unselfish service, but omits mention of most of the President's own continuous and arduous labors in our behalf. Nowhere does he mention his traveling up and down the State, speaking before meetings of District Branches and county societies, his innumerable conferences with

government officials and boards, his endless correspondence, letters to the press, interviews, after-dinner addresses, the thousand and one items of personal sacrifice which he takes for granted under the code of *noblesse oblige*. For us to pass them by without a word would be ingratitude indeed.

The Society has exercised noteworthy discrimination in selecting for the presidency a succession of men of distinguished professional and administrative ability. Dr. McGoldrick carries on the brilliant record of a long line of very able predecessors. The President is the representative of and spokesman for the medical profession in the State; by his own character, presence, and prestige, he enhances the respect in which medicine at large is held throughout the laity. This Reference Committee speaks for the inarticulate body of practitioners of medicine throughout the State in expressing to Dr. McGoldrick the Society's recognition of the tremendous personal sacrifices he has made for it during this year of ordeal, and its appreciation.

I move the adoption of this section of the report of the Reference Committee.

... The motion was seconded, and as there was no discussion, it was put to a vote, and was unanimously carried. ....

DR. FREY: Your Reference Committee had referred to it also the remarks of President-Elect Bauckus.

SPEAKER BAUER: Yes.

DR. FREY: President-Elect Bauckus in his address to the House of Delegates reviews the activities of the State Society and points out certain important features which will be stressed during his administration—namely: provision for returning to practice discharged medical officers of the armed forces; continued support of the A.M.A., particularly its Council on Medical Service and Public Relations; opposition to the Basic Science Law on the ground that it will not eliminate chiropractic, but will cause it to be recognized by licensure (this has been the experience in those states having basic science laws); continued development of post-graduate instruction in cooperation with the State Department of Health.

The President-Elect feels very strongly that tuberculosis should be treated as a contagious disease, patients to be isolated from contacts and given necessary financial aid.

He urges that the Planning Committee on Medical Policies be continued.

He would have the members of the Society co-operate in the E.M.I.C. plan and hope for improvement in its medical provisions, emphasizing the supposedly temporary nature of this wartime setup.

The Reference Committee looks with favor on Dr. Bauckus' recommendation that

"we . . . cooperate to the full in the development of sound health programs"

set up by the State government, but because of the ambiguity of this statement we would urge caution in endorsing any plan before it has received approval by this House of Delegates.

Dr. Bauckus gives it as his personal opinion that the practice of compensation medicine in the State of New York is important enough to warrant the employment of a state-wide director. This Reference Committee cannot express an opinion on this matter, which is being considered by another reference committee.

Dr. Bauckus announces the merger establishing the United Medical Service Corporation, providing

prepaid medical insurance for the seventeen southern counties of the State, and he recommends the organization of a bureau to study and plan state-wide medical insurance plans.

In condemning the medical provisions of the Wagner-Murray-Dingell bill as an untried experiment, he states, "It is unfortunate that the leaders of labor seem willing to so soon forsake our proved care for this will-o'-the-wisp. For I believe we still are, and always will be, the most practical and understanding friend of the laboring man and his family."

Your Reference Committee commends the address of the President-Elect as indicative of his thorough grasp of the business of the Society, gained through his many years of active service. It feels that the members of the Society may disperse to their homes secure in the knowledge that for another year the Society is being guided by a leader who walks with God and quotes His Holy Word.

I move the adoption of this portion of the Reference Committee's report.

... The motion was seconded, and as there was no discussion, it was put to a vote, and was unanimously carried. ....

DR. FREY: Now I move the adoption of the Reference Committee's report, signed by W. Guernsey Frey, Jr., Robert C. Simpson, Horace E. Ayres, Charles A. Prudhon, and John E. Wattenberg, as a whole.

... The motion was seconded, and as there was no discussion, it was put to a vote, and was unanimously carried. ....

SPEAKER BAUER: Thank you, Dr. Frey.

#### Section 76. (See 13, 60, 81)

#### Report of Reference Committee on Constitution and Bylaws Amendments—Redistribution of County Delegates; Expenses of A.M.A. Delegates

SPEAKER BAUER: Dr. Holcomb, we threw you out yesterday, but we will let you come back now.

Dr. Holcomb is Chairman of the Reference Committee on Constitution and Bylaw Amendments. You recall that we started to consider his report yesterday, and it was postponed until there was a greater representation present today.

You may begin the report from the start again, as I doubt whether we remember exactly what was said last night.

DR. FREDERIC W. HOLCOMB, *Ulster*: In regard to the proposed amendment to the Bylaws, Chapter II, Section 1, which is as follows:

"WHEREAS, the recently enacted reapportionment bill is based upon the population ratio and will thereby cause a redistribution of delegates from the component medical societies to the House Delegates to the Medical Society of the State of New York; therefore be it

"Resolved, that the number of delegates from any component medical society be not reduced from their present number unless there has been a material reduction of the number of physicians in the area of any county medical society,"

your Reference Committee disapproves this proposed amendment for the following reason: The wording of this amendment is indefinite as to this portion—"unless there has been a material reduction of the number of physicians in the area of any county medical society." No definition of the word "material" is given.

I move the adoption of this portion of the report.

... The motion was seconded. ....

SPEAKER BAUER: The Reference Committee

recommends disapproval of the proposed amendment. The motion is on the adoption of the Reference Committee's report, which carries with it disapproval of the amendment. Is there any discussion?

DR HARRY ARANOW, *Bronx* Just a point of information. What is the legal effect of this? I had an idea that according to our constitution any group can propose an amendment and that it has to come before the House for consideration the next year.

SPEAKER BAUER Right and it is before the House right now.

DR ARANOW But was it proposed last year?

SPEAKER BAUER It was proposed last year and because there were two amendments on the same subject and they were both indefinite it was referred to a reference committee for clarification, and it is now before the House.

Is there any other discussion?

The question was called for, and the motion was put to a vote, and was carried.

SPEAKER BAUER The motion is carried and the amendment is lost.

DR HOLCOMB In regard to the proposed amendment to the Bylaws Chapter II Section I which was introduced by Dr Albert Cinelli and which provides

"Each component county society shall be entitled to elect as many delegates as there shall be State assembly districts in each county at the time of the election but each component county medical society shall be entitled to elect at least one delegate."

Is to be amended to read,

"Each component county society shall be entitled to elect delegates in proportion to the number of doctors practicing at the time of election but each component medical society shall be entitled to elect at least one delegate."

Your Reference Committee disapproves this amendment for the following reasons. The wording of the amendment is too vague and indefinite, as it states that 'Each component society shall be entitled to elect delegates in proportion to the number of doctors practicing in the county.' Your Refer-

at the word  
such propor  
of the county  
rather than

of the report  
s there was no

discussion, it was put to a vote, and was carried.

SPEAKER BAUER The motion is carried, and the amendment is lost.

DR HOLCOMB It is proposed to amend the Bylaws, Chapter V, Section I, which is as follows:

'The delegates to the American Medical Association who have attended each session of the House of Delegates of that Association and who shall have filed with the Secretary evidence of such attendance shall be allowed the actual cost of railroad transportation and Pullman accommodations to the place of meeting and return.'

by inserting in its place

The delegates to the American Medical Association who have attended each session of the House of Delegates of that Association and who shall have filed with the Secretary evidence of

such attendance shall be allowed traveling expenses."

Your Reference Committee approves the proposed amendment and moves its adoption.

I believe that will have to be acted on first before a further recommendation is put before you, or shall I give you the further recommendation to the Council now before you act on this portion?

SPEAKER BAUER Does it pertain to that same amendment?

DR HOLCOMB It does.

SPEAKER BAUER Let us have your further recommendation first, then, before we act on this portion of the report.

DR HOLCOMB We further recommend to the Council that the term "traveling expenses" be considered to include the cost of one first-class round trip railroad fare with cost of Pullman lower berth from home to place of meeting and, in addition a per diem allowance of \$10 while acting as a Delegate.

We felt we should specify what that term meant in some definite way.

SPEAKER BAUER That is to clarify the intent of the Reference Committee?

DR HOLCOMB Yes.

SPEAKER BAUER Are you moving that as an instruction to the Council or as an amendment to the Bylaws, to be incorporated in the Bylaws?

DR HOLCOMB That is a recommendation to the Council not to be incorporated in the Bylaws.

DR JAMES F. ROONEY, *Albany* There is only one thing that occurs to me, and that is the reference to the review by the Secretary. Taken in connection with the rest of the text that could apply either to the Secretary of the American Medical Association or to the Secretary of the Medical Society of the State of New York. I would move in view of the fact that the Bylaw is now up for discussion and may be amended from the floor, that we add the words "of this Society" after the word "Secretary" in other words, that evidence of attendance shall be given to the Secretary of this Society.

SPEAKER BAUER Is there any objection to incorporating that clause in the amendment?

DR HOLCOMB None from the Reference Committee. It is merely a clarification.

DR JAMES F. ROONEY Exactly.

DR GEORGE W. KOSMAK I have another—

SPEAKER BAUER Does your point apply to this suggested amendment?

DR KOSMAK No.

SPEAKER BAUER Let us dispose of one at a time then. Is there any objection to clarifying the proposed amendment by the inclusion of that phrase?

There was no dissent expressed.

SPEAKER BAUER The Chairman hears none, and it will be so incorporated.

DR KOSMAK As I understood the reading of the proposed amendment, the delegate is required to present evidence of his attendance to the Secretary of the State Society. Would it not be much better to accept the roll call of the Secretary of the American Medical Association as evidence of a delegate's attendance? It is rather difficult for the delegates individually to present this evidence. It could be taken from the records of the American Medical Association itself, and this would be much simpler.

DR ARTHUR J. BEDELL, *Albany* The whole thing can be phrased in words like these "as certified by the Secretary of the American Medical

Association to the Secretary of the New York State Medical Society." That is the legal form.

SPEAKER BAUER: The suggestion of Dr. Bedell is that it be still further amended by stating that the certification shall be by the Secretary of the American Medical Association to the Secretary of the Medical Society of the State of New York. Is there any objection to incorporating that in the amendment?

DR. ROONEY: It seems to me that we have had three suggestions as to a change in the Bylaws, which have a legal import. I would make the motion that these recommendations be conveyed to the Reference Committee, that they incorporate these changes, if there is no objection, in the proposed Bylaws, first consulting the Counsel of the State Society as to the proper legal terms to be used, and then re-present the matter to the House. That should not take a long time, and it can be re-presented later this morning.

SPEAKER BAUER: In other words, you are moving that it be recommitted?

DR. ROONEY: Yes.

SPEAKER BAUER: Is there objection?

.... There was no dissent. ....

SPEAKER BAUER: The Chairman hears no objection, so it is recommitted.

#### Section 77. (See 61, 34)

#### Report of Reference Committee on Report of the Council—Part XI: Malpractice Defense and Insurance and Legal Counsel (Resolutions Included)

DR. MOSES H. KRAKOW, *Bronx*: Your Reference Committee has reviewed the report of the Council Committee on Malpractice Defense and Insurance, Dr. Clarence G. Bandler, *Chairman*.

We note with satisfaction that the following reductions and other changes have become effective for all policies dated after April 1, 1944:

(a) The base premium for a minimum policy reduced from \$32 to \$30.

(b) The table for excess of the minimum reduced by about 10 per cent.

(c) The surcharge on added protection on account of "cosmetic" plastic surgery reduced from 50 per cent to 10 per cent.

(d) The surcharge for including protection for x-ray therapy reduced from \$30 to \$15 for minimum limits.

(e) A further reduction for members in the armed forces to 30 per cent of the premium—liability is, however, limited to claims within continental limits of the United States.

(f) Inclusion of liability on account of the acts of an insured copartner.

We endorse the Committee's recommendation that uninsured members of the State Society secure immediate protection in the group insurance plan, as well as the oft-repeated warning to the members to use the greatest care in avoiding thoughtless criticism of their conferees, which continues to be the largest inspiration for malpractice actions.

It is evident from Paragraphs 5 and 6 of the Report that the Insurance Committee is apprehensive lest the Group Malpractice Insurance Plan, which has been in existence for over twenty-three years, may be disrupted and this important function of the State Society nullified. It is also evident that the Insurance Committee senses a definite unrest among members of some of the county societies who would go outside of the Group Plan to secure

malpractice protection. A reference is made to activities of other insurance carriers who, from time to time, decide to enter the malpractice insurance business in New York State in competition with the Group Plan.

Your Reference Committee is in agreement with the Committee's comment that the group insurance plan is an important function of the State Society and that all component county societies should support the Group Plan.

We, therefore, suggest that attempts be made to increase the list of participants in group insurance by more active publicity and solicitation.

Your Reference Committee recommends that the Council Committee on Malpractice Defense and Insurance proceed to make a survey of the entire malpractice insurance situation and bring in recommendations to the Council.

I move the adoption of this report.

.... The motion was seconded. ....

SPEAKER BAUER: You have before you the Report of the Reference Committee which recommends, after surveying the work of the Committee for the past year, that the Council Committee on Malpractice Defense and Insurance survey the whole situation relative to malpractice insurance and render a report to the Council. Is there any discussion on that motion?

DR. THOMAS M. D'ANGELO, *Queens*: I should like to ask a question. I did not quite get the last part of the report as read. Does it refer the matter back to the Council Committee on Malpractice Defense and Insurance or to a special committee?

SPEAKER BAUER: The Council Committee, as I understood it.

DR. KRAKOW: Yes, the Council Committee on Malpractice Defense and Insurance is to make a survey of the situation and report to the Council.

DR. D'ANGELO: Then I would like to speak on that.

SPEAKER BAUER: You may have the floor.

DR. D'ANGELO: Mr. Speaker and Members of the House, I have introduced a resolution on this very matter, and it will probably come up later, but in adopting this part of the Reference Committee's report you will have to consider a portion of the resolution that I brought in, and that is why I am speaking on it now.

Your Reference Committee recommends that the matter be studied again through the Committee on Malpractice Defense and Insurance of the Council. I imply no criticism whatsoever as far as that Committee of the Council is concerned, but I feel that the Council should appoint a subcommittee to study the entire matter, that subcommittee to report to the Council on its findings. My resolution proposes that a copy of such findings be sent to each county medical society. I think this matter is very important.

Shall I speak on that resolution or wait until it comes up?

SPEAKER BAUER: I take it you are in accord with the Report of the Reference Committee except that part of it which recommends that the matter be studied by the Council Committee on Malpractice Defense and Insurance, and instead you wish a separate committee to do that?

DR. D'ANGELO: That's it exactly.

SPEAKER BAUER: Then it will be your privilege to move an amendment to the report accordingly, if you so desire.

DR. D'ANGELO: I, therefore, move to amend

the report to the effect that a special committee of the Council be appointed to study this matter, and that this special committee then make its report to the Council itself.

The motion was seconded.

**SPEAKER BAUER** You have before you for consideration the amendment to the Committee's report, to the "Council Committee on Malpractice Defense and Insurance." The amendment is to delete and insert the following: "The Council shall appoint a special committee to study this matter."

**DR. FREDERICK W. WILLIAMS, Bronx** Speaker and Members of the House of Delegates, this is also closely related to the instruction which we were given by our county society. Our resolution, as you remember, distinctly felt that the Insurance Committee had delegated too much of its power to our Insurance Representative. I am quite sure that, in keeping with the intent of our resolution, to refer this directly or give a dictate to the Insurance Committee to investigate the field would be quite inadequate.

**SPEAKER BAUER** Is there any further discussion on the amendment? If not the question is, shall the committee's report be amended by substituting a special committee of the Council for the Council Committee on Malpractice Defense and Insurance?

All those in favor of the amendment will please say "Aye," those opposed, "No." The amendment appears to be, and is declared, lost. Does anyone question that ruling?

There was no response.

**SPEAKER BAUER** Therefore, the question now is on the adoption of the Reference Committee's report.

**DR. EDWARD P. FLOOD, Bronx** May I suggest an amendment to the Reference Committee's report?

**SPEAKER BAUER** You may.

**DR. FLOOD** The suggestion is that it be publicized, that it is the implied duty of every official of every subsidiary or county medical society to encourage adherence of the membership to the Group Plan until such time as it has been determined that the policy of this House is no longer to support the Group Plan.

**SPEAKER BAUER** Do you make that in the form of an amendment?

**DR. FLOOD** Yes.

**SPEAKER BAUER** You have the amendment proposed by Dr. Flood, is it seconded?

It was seconded by several.

**SPEAKER BAUER** Is there any discussion on the amendment?

**DR. JOSEPH A. GLIS, Essex** Has this House of Delegates the right to order the officers of the various county societies to do a certain thing? I raise that as a point.

**SPEAKER BAUER** It was not to order them. It was to call their attention and suggest to them that they do that correct. Dr. Flood?

**DR. FLOOD** Yes.

**SPEAKER BAUER** The substance of the motion was that the officers of the county societies should be asked to bring this matter to the attention of the county societies and urge all members to take part in the Group Plan so long as the State Society supported the Group Plan principle.

Is there any further discussion on the amendment?

The question was called for, and the motion was put to a vote, and was carried.

**DR. BAUER** The motion is carried, and the question now before you here any further

or, and the motion was put to a vote, and was carried.

**SPEAKER BAUER** The report as amended is adopted.

Will you continue Dr. Krakow?

**DR. KRAKOW** This is on the Report of the Legal Council. The report of the activities of the legal department of the Medical Society of the State of New York is for the period from February 1, 1943, to February 1, 1944, and covers the activities of the present Council, Mr. William F. Martin, and also two and one-half months during which his predecessor, the late Lorenz I. Brosnan, was Council. The report is in three parts: (1) litigation, (2) counsel work, and (3) legislative advice and activity.

**1 Litigation**—We note that during the reporting period 87 suits were commenced and 92 disposed of as follows: settled, 37, terminated in favor of the physician, 52, judgment for plaintiff, 3.

The figure of the new actions is substantially lower than that of a year or two ago. It is to be noticed, however, that many member physicians are now in litigation because of statutory changes.

**Insurance Plan**—The Insurance Plan sponsored by the Medical Society, pointing out the frequent law suits against uninsured doctors.

The 87 cases mentioned do not include a number of outstanding claims on which suits may be instituted ultimately. The Council did a great deal of preventive work, which by consultation with many of our attorneys helped to avoid cases which would have been appreciated by the members of the Yorkshire Indemnity Company. Bandler and his Committee.

**2 Counsel Work**—The Council has attended to all the legal matters of the State Society as well as those of the component county societies. The Council drew the contracts between the Society and Dr. Joseph S. Lawrence, its Executive Officer, Dr. Peter Irving, Secretary and General Manager, and Mr. Dwight Anderson, Director of the Public Relations Bureau and Business Manager of the Journal and Directory.

The Council has also responded to the numerous requests for opinions, both oral and in writing, on many topics, about the legal responsibility of physicians.

**3 Legislative Activities and Advice**—During the sessions of the State Legislature in Albany in 1943 and 1944, the Council examined a number of bills affecting the medical profession and gave advice in respect thereto, he also has frequently conferred with Dr. Lawrence in regard to these bills. Mr. Clearwater, the attorney, has attended the conferences of the Committee on Legislation with the chairmen of the county societies legislative committees in Albany.

The report is close to the work of his assistance of members both in court and in malpractice actions. The next...

.... The question was called for on the amendment, and the amendment was put, and was lost. . .

**SPEAKER BAUER:** You have now before you the report of the Reference Committee as amended by Dr. D'Angelo's motion. Is there any further discussion?

.... The question was called for, and the motion as amended was put to a vote, and was carried. ....

**DR. KRAKOW:** The following resolution was introduced by Dr. F. Williams of the Bronx County Society:

"WHEREAS, there is an Insurance Committee of the Medical Society of the State of New York; and

"WHEREAS, one of the functions of this Committee is to supervise the Group Plan of Malpractice Insurance in order to provide for the membership protection in a reliable and sound company at as low a rate as possible; and

"WHEREAS, this Committee has failed to function satisfactorily but has evaded its responsibility by the abdication of its function to the Insurance Representative; and

"WHEREAS, an insurance company other than that under the Group Plan, reliable and sound, has entered the field in our county; and

"WHEREAS, this company has sold similar protection to individuals at a substantially lower rate than that under the Group Plan; and

"WHEREAS, this condition has disrupted the Group Plan in our county; and

"WHEREAS, this condition will eventually result in disunity throughout the State Medical Society; therefore be it

"Resolved, that the Bronx County Medical Society instructs its Delegates to the State Society Convention to bring this matter before the House of Delegates at its 1944 meeting; and be it further

"Resolved, that the present leading competitor in the field of malpractice insurance be given a hearing and that each county society be informed of the reasons for rejecting or accepting this company; and be it further

"Resolved, that the Insurance Committee of the State Society be directed to meet with other active competitors in malpractice insurance and submit regular reports on these meetings; and be it further

"Resolved, that copies of these resolutions be sent to the county medical societies throughout the State immediately."

Your Reference Committee on the Report of the Council, Part XI, has recommended a comprehensive survey of the Group Malpractice Plan. We feel that the substance of this resolution has been incorporated in the recommendations of your Reference Committee, and therefore no action need be taken on this resolution.

I move the adoption of this report.

.... The motion was seconded, and as there was no discussion, it was put to a vote, and was carried. . .

## Section 78

### Report of Reference Committee on Report and Supplementary Report of Council—Part VIII: Legislation

**DR. EUGENE H. COON, Nassau:** The Reference Committee on Legislation has studied the Report of the Council Committee on Legislation, its supplementary report, and the several legislative bulletins which it has issued.

We wish to commend the legislative subcommittees for their earnest work. Dr. Leo F. Simpson was appointed chairman of a subcommittee to study the merits of the Basic Science Laws by our Past-President, Dr. George W. Cottis. Dr. Simpson's committee, in its report, emphasized that the educational requirements demanded for licensure to practice medicine or the healing art should be met by all candidates. These standards should not be lowered. A basic science law is not needed to curb the activities of the various illegal cultists. A proper enforcement of the law, as it now exists, would be entirely adequate. Dr. Ralph Todd acted as chairman of the chiropractic subcommittee at the request of our President, Dr. Thomas A. McGoldrick. Dr. Todd reported for his committee that the standards of those who practice medicine should ever reach for higher levels, never for lower ones. All who practice the healing art in our State should meet the qualifications as set down in the laws and the regulations of the medical and osteopathic practitioners. The maintenance of high uniform standards for all medical practitioners is insisted upon.

During the 1944 session of the Legislature many bills which related to public health, medical education, medical practice, and workmen's compensation were introduced. The commissioners appointed to investigate the problems of workmen's compensation under the Moreland Act reported to the Governor, and a large number of bills were introduced to amend the Workmen's Compensation Act. For the greater part they were hastily enacted into law. The methods of authorizing physicians to do compensation work and of licensing compensation medical bureaus and laboratories in New York City has been changed, as reported this morning by our President, Dr. Thomas A. McGoldrick. We earnestly hope that this will be an improvement on the previous method. Time will tell.

We feel that the newly enacted amendments to the Workmen's Compensation Law should be supported, with the reservation that this support will be withdrawn unless, after the new law has been in operation and experience demonstrates a need for revision, the recommendations of the medical profession are given proper hearing and consideration.

The joint legislative committee to investigate the practice of chiropractic reported to the Governor. A bill which embodied the committee's recommendations was introduced in the Senate and the Assembly. It was recommitted in the Assembly, where it was killed by adjournment.

Quoting from the Report of the Council Committee on Legislation:

"At the conference of the county societies' legislative chairmen held in Albany on February 29, after long debate on both the basic science law and chiropractic, a motion was carried instructing the State Legislative Committee to prepare and offer amendments to the chiropractic bills."

Your Reference Committee is in strong opposition to this procedure. We say to the House that there can be no compromise. We must continue with every device at our command to oppose legislation that would legalize chiropractic. It is easy to rationalize appeasement by terming it expediency or practicality, but it should be recognized for what it is: sacrifice of principle and betrayal of a sacred trust. As the guardians of the public health we must aim to defeat, not amend, chiropractic

bills. Here is the ideal application of the principle enunciated by Dr. Simpson's committee: proper enforcement of the present Medical Practice Act.

We heartily agree with the Council Legislative Committee that it is regrettable that some legislators could report on the floor of their chamber that they had been approached by chiropractors to support their bill, but had not been requested by a physician or other person to oppose the bill. We suggest that each delegate bring this to the attention of his respective society and its legislative

The enactment of several welfare bills furthers the advancement of state medicine.

Your Reference Committee compliments the Council's Committee on Legislation, Dr. John L. Bauer, Chairman, Dr. Walter W. Mott, and Dr. Leo F. Simpson, for its untiring and industrious efforts during the past year. We also acknowledge the splendid accomplishments of Dr. Joseph Lawrence, Executive Officer.

This report is respectfully submitted by the committee consisting of Eugene H. Coon, Chairman, Abraham Koplowitz, James S. Lyons, Joseph C. O'Gorman, and Ezra A. Wolff.

I move its adoption.

.... The motion was seconded. ....

**SPEAKER BAUER:** You have before you the Report of the Reference Committee on Legislation. Is there any discussion?

**DR. CHARLES GULLO, Livingston:** There is a resolution before one of your reference committees, on which you have not as yet had a report, that touches upon the Basic Science Law, and I move, in view of the fact that that report has not yet come in, that that part of the Reference Committee's report which says it is the opinion of the Committee not to approve the Basic Science Law be postponed until such time as we discuss the report on the resolution.

The reason that I ask you to do that is that I have here the full report of Dr. Simpson, Dr. Mott, and Dr. Bauer, which was submitted to the Council. As you know, this House instructed this Committee to study the efficacy of the Basic Science Law as it applies to New York State and to the particular conditions that exist in this State. I will read to you part of that report: "We have carefully considered it in its relation to the problem of the licensing of chiropractors."

As just reported by another committee, and as voted, we are against the licensing of chiropractors in any shape, form, or manner. We have always been that way in our feelings. Therefore the ... but, unfortunately the ... ider it in its relation to ... respect to the greater scope of the Basic Science Law—namely, whether it will prevent and eliminate all cults in this State.

**SPEAKER BAUER:** Do you make a motion, Dr. Gullo?

**DR. GULLO:** Yes, I am making the motion that this be tabled until the other Reference Committee reports on the resolution that was presented in regard to the Basic Science Law.

**SPEAKER BAUER:** That is not tabling, that is postponing action.

**DR. GULLO:** Right, postponing action.

**SPEAKER BAUER:** Dr. Gullo moves that the adoption of this report be postponed until after the resolution on the Basic Science Law is returned by the other reference committee. Is there any discussion on the postponement?

**DR. EZRA A. WOLFF, Queens:** It seems to me that we postponed the other resolution to await the completion of this report.

**SPEAKER BAUER:** The one you are now referring to is the resolution pertaining to the enforcement of the Medical Practice Act, as reported on by the Reference Committee on New Business B. That was postponed until after the Reference Committee on Report of the Council, Part VIII, on Legislation, was received.

**DR. WOLFF:** Right.

**SPEAKER BAUER:** But Dr. Gullo is referring to the resolution presented by Dr. Kneckerbocker on the Basic Science Law, and which has not been reported on as yet. Am I right?

**DR. GULLO:** Yes.

**DR. THOMAS M. D'ANGELO, Queens:** I disagree with Dr. Gullo as to the effect of adopting this report.

The adoption of this report does not necessarily mean that the Basic Science Law cannot be brought before this body. I do not think we should inject the Basic Science Law into this report, but we should consider it when the Reference Committee reports on the resolution.

**DR. JAMES F. ROONEY, Albany:** I second the remarks of the previous speaker. I don't think we should have all of these postponements. It is simply going to prolong the session of the House of Delegates. Let us proceed with the consideration of this report and take up the consideration of the Basic Science Law when that Reference Committee reports.

**DR. GULLO:** Very well, I withdraw my motion.

**SPEAKER BAUER:** Is there any objection to the withdrawal of the motion?

.... There was no dissent expressed. ....

**SPEAKER BAUER:** There appears to be none; therefore, we will proceed with the original motion, which was the adoption of the report of the Reference Committee on the Report of the Council, Part VIII, on Legislation.

**DR. ARTHUR J. BEDELL, Albany:** I should like to call the attention of the House to what seems to me to be a ... policy started by the ... relation.

**DR. ROONEY:** ... it is the report of the ... chairman's meeting at Albany, to which you are referring, and which is not mandatory.

**DR. BEDELL:** May I read it, sir?

**SPEAKER BAUER:** Go ahead.

**DR. BEDELL:** "At the Conference of the County Societies' Legislative Chairman held in Albany on February 29, after long debate on both the Basic Science Law and chiropractic, a motion was carried instructing the State Legislative Committee to prepare and offer amendments to the chiropractic bills"—something that this Society should never stand for

authorized ... ho is not therefore, ... legates. I, this Reference Committee in stating that it is in strong opposition to this procedure. I have taken this time, Mr. Chairman, to draw attention to that valuable report of the Committee, and to ask that special attention be paid to it in the future. (Applause)

**SPEAKER BAUER:** Is there any further dis-

cussion on the adoption of the report of the Reference Committee?

.... The question was called for, and the motion was put to a vote, and was carried. ....

#### Section 79. (See 62)

#### Report of Reference Committee on New Business A—Minimum Medical Fee Schedule of the Workmen's Compensation Law

DR. JOHN D. CARROLL, *Rensselaer*: This report is on the resolution presented by Dr. A. Kopolowitz, of Kings County, regarding Minimum Medical Fee Schedule of the Workmen's Compensation Law, reading:

"WHEREAS, the minimum Medical Fee Schedule of the Workmen's Compensation Law was established by the Industrial Commissioner of the State of New York during normal times; and

"WHEREAS, on and after May 15, 1942, the hospitals of the State of New York were granted an increase in fees by the Industrial Commissioner following a conference and agreement by the representatives of the compensation insurance carriers and the Hospital Association of New York State; and

"WHEREAS, the cost of living has increased within the past few years; therefore be it

"Resolved, that the Medical Society of the State of New York take such appropriate action as is necessary with the Industrial Commissioner of the State of New York and the representatives of the compensation insurance carriers that an increase be granted to the medical profession for fees in the present 'Minimum Medical Fee Schedule.'"

The Committee approves this resolution, and I move its adoption.

.... The motion was seconded. ....

SPEAKER BAUER: You have before you the recommendation of the Reference Committee which calls for the approval of this resolution. Is there any discussion on it?

DR. ARTHUR J. BEDELL, *Albany*: I ask for the deletion of one word, and that is "minimum."

While I have the floor, I wish to call to the attention of the House that we adopted this Compensation Law during my presidency and not Dr. Sondern's. I then spoke against this fee bill and said that we would regret it, for what we called minimum would be considered maximum. If you will look over your legislative enactments, you will find that shortly after the adoption of this minimum fee schedule a little rider to the Law was passed through the Legislature, making it the maximum.

Therefore, I don't like the word "minimum," and ask that it be deleted—or fold your hands and remember it will go down all the time. I am heartily in favor of the resolution otherwise.

SPEAKER BAUER: Dr. Bedell moves to amend the resolution by striking out the word "minimum." Is there any objection?

.... There was no dissent expressed. ....

DR. CARROLL: None on the part of the Committee.

SPEAKER BAUER: The Chairman hears none, and it is so amended.

The question is on the adoption of the report as amended. Is there any further discussion?

.... The question was called for, and the motion was put to a vote, and the resolution as amended was adopted. ....

#### Section 80. (See 65)

#### Report of Reference Committee on New Business A—Basic Science Law

DR. JOHN D. CARROLL, *Rensselaer*: This report is on the resolution, slightly amended with the consent of the introducer, presented by Dr. H. J. Knickerbocker, of Ontario County, on the Basic Science Law, reading:

"WHEREAS, experience has shown that existing laws in New York State have proved ineffective in preventing the growth of the illegal practice of medicine; and

"WHEREAS, it is in the interest of the public health that steps be taken now, directed towards the eventual elimination of illegal practitioners through the enactment of laws which would effectively raise the degree of education of such practitioners to such a level that they might justly become legal practitioners, be it

"Resolved, that the House of Delegates of the Medical Society of the State of New York instruct its Legislative Committee that it have introduced a bill at the next session of the Legislature of the State of New York providing for the enactment of new legislation to the Education Law of New York State to guard against, and to prevent growth of, all illegal practitioners, and that such proposed legislation be known and designated as the Basic Science Law, which shall provide, as a prerequisite for license to practice the Healing Art, satisfactory study and examination in the basic sciences—namely, anatomy, physiology, physiologic chemistry, bacteriology, pathology, and hygiene."

Your Committee sees no objection to a Basic Science Law as stated in this resolution.

It is not a recognition of any cult, and it would not defeat any efforts to thwart the licensing of any or all cults.

Your Committee unanimously approves of this resolution, and I so move.

.... The motion was seconded. ....

SPEAKER BAUER: You have before you the adoption of the report of the Reference Committee, which recommends the approval of this resolution. Is there any discussion?

DR. JACOB WERNE, *Queens*: The approval of this action would be one of the most pernicious steps this Society can take. It is true that in the wording of a Basic Science Law there is no implicit approval of any cult, but the connotation of the word is often more important than the denotation, and by permitting these people to prepare for an examination in schools that are not recognized we are opening the door wide. I wonder how many of you gentlemen know that in the Los Angeles County Hospital the surgical service is divided into regular surgery and osteopathic surgery, and that the gynecologic service is divided somewhat in the same fashion; the same is true of the dermatologic service, and so on; and we can see the day when in our county hospitals in this State we will have chiropractic services.

We either believe that no one has a right to practice the healing art without adequate preparation or we don't believe that. Basic science knowledge is only one of many facets of the preparation for the practice of the healing art. We should not compromise. We absolutely must defeat this or the next day we will have chiropractors being especially groomed to pass these examinations. (Applause)

DR. JAMES F. ROONEY, *Albany*: I think that to adopt this measure would be one of the most reactionary thing do. I entirely stated by the lessness in relation to apparently overcoming many of our men associated with legislative enterprise in the last three or four years, and in my opinion has been largely due to laziness of mind. This Society has been able to defeat through its legislative representatives all attempts of the chiropractors to be licensed ever since 1914. Now, gentlemen, that was thirty years ago. We have had this fight year after year ever since. True, some of us are getting tired of the fight every year, but if we are going to stand on principle that fight must continue without any compromise. There has never been any compromise before. There should never be any compromise on the training of educated physicians.

Basic science will not dispose of the main evil of chiropractic today, because the moment that a basic science law is enacted the chiropractors will be enabled to put in the so-called grandfathers' clause: that every man who is now practicing and has been practicing in this State for three or five years will be licensed as a chiropractor without any examination.

Gentlemen, I have gone through the whole osteopathic fight. I know just exactly how, and when, and why the osteopaths were licensed in this State. They were licensed for one very good reason. The wife of the then Governor of this State, a man who afterwards became a justice of the Supreme Court of the United States, had some leg disability, and the osteopaths pulled her leg, so to speak. (Laughter) Apparently it was enjoyable, and perhaps effective, but by his pressure upon her leg and the most eminent in the State of New York the osteopaths were licensed.

What happened? A statement was made before that Committee that once they were licensed they enactment year after to cover practically the that has occurred.

A basic science law will not cure this evil. It has not cured it in California. It has not cured it in any of the fourteen states that have adopted it. I hope that this House will vote down this recommendation. (Applause)

DR. H. J. KNICKERBOCKER, *Ontario*: May I say that I introduced this resolution by request? (Laughter)

DR. ROONEY: I want to say in answer to Dr. Rooney's remarks, I want to say

as there are at present. Remember, the osteopaths have their own board.

Whether you like it or not, I feel, and the legislators that I have spoken to feel, that sooner or later the chiropractic bill is going to pass. We are not going to discuss here whether chiropractors should or should not be licensed to practice. We are here for a practical purpose, and, although I may be wrong, if you go on the premise that the chiropractors are going to be licensed sooner or later, because they are already licensed in forty-six states, then you are opening the door for chiro-

practors to be licensed without such preparation. If we have a basic science law, then, if the chiropractors are licensed at some future date, they will have to meet those basic science requirements. If you have chiropractors licensed now, they may not have to meet any basic science requirements.

Let me cite Minnesota. Minnesota had 650-odd chiropractors in 1927, when the Basic Science Law was enacted. Since that time, since 1927, only 61 chiropractors have been able to pass that examination. Of course you would say that is 61 too many, but the number has gradually been going down. It shows there are fewer, and if they keep on it will have been, in fifteen or twenty years the problem in Minnesota will have vanished.

If we enact a basic Legislature sees fit to on, a basic science law would not only the of chiropractors, but it would at least give the groundwork for any chiropractor to come in and take this examination, and if a chiropractor has to study to 1 of years I and go on Let us out of the now, so that anyone who wants to practice the healing art in New York State at least must have those basic requirements.

DR. STEPHEN H. CURTIS, *Rensselaer*: Can I ask the privilege of the floor for Dr. Hannon, who is the Secretary of the Medical Examining Board? He can explain this, I think, better than most of us.

SPEAKER BAUER: Is the House willing to grant the privilege of the floor to Dr. Hannon?

DR. HARRY ARANOW, *Bronx*: I so move. SPEAKER BAUER: If there is no objection, we will be glad to hear from him. (Applause)

DR. ROBERT R. HANNON: May I first remark that I am not here as a representative of the Department of Education, and anything I say does not represent the views of the Department necessarily. They are my personal views.

I have watched with great interest the basic science laws in other states, and have considered the problem in New York State both from the standpoint of enforcement of our laws and breaking up illegal practice and also in regard to the practice of cults that are not recognized under the present New York law.

I do not believe that the answer to your problem is a basic science law. Our whole purpose is the protection of the public. You, as a Society, are interested in that protection of the public. You have in the past held to standards which you thought were a protection to the public in anything that pertained to the treatment of disease or physical conditions in members of the population of the State. I do not believe that you want to go on record now as being willing to lower your standards, as you will if you set up approval of any of these things or if you go on record as approving of these measures. Then you are approving a standard which I think does not meet your ideas of the protection of the public, and which certainly is not equivalent to our present standards.

The idea of a basic science law has been pre-

sented in many states and passed in many states more as a stopgap method of legislation, as an attempt to solve their problems. From my information from many states they are very often sorry that they adopted such a measure after they have done so.

It would depend, of course, in all these things, on the type of law that is put through. If you think that you will put through a law under which a group of physicians are going to examine everybody that is going to practice the healing art, I think you are anticipating too much. In the majority of states the examining boards are made up of nonmedical men. They are in some states made up even of only three persons, usually not M.D.'s

Such an examination not only sets the basis for licensure by the subsequent boards in whatever field it is, such as the person who passes that basic science examination then must take the licensing examination of his particular group, but it opens up the field right then and there to every cult that cares to come into practice. Your chiropractors will then have an examining board from which they will take the candidates from the basic science examination. Your nephropaths, your naturopaths, and so on, will each have their own examining boards. That has been the story in most states where the basic science law has been adopted. If you look at the statistics from a certain angle, it is true that the number of chiropractors that are practicing in some of those states has been reduced since they have had their basic science law, but that has been essentially because the chiropractors themselves have failed them in their board rather than that they have failed in the basic science examination to a great extent. It is because it becomes a closed corporation, more or less, after they get a certain number licensed. Then it becomes very difficult for additional ones.

We have that situation at the present time in physiotherapy. We have a license examination for physiotherapists, but the standards are such that nobody has been able to meet those requirements, and there has not been a person in the physiotherapy examination for six or eight years, because no one met the requirements; nevertheless, we have quite a few thousand physiotherapists, technicians who are going on and practicing in doctor's offices, institutions, and so on. It has not stopped people from going into the field of physiotherapy in New York State, even though we have only 300 licensed physiotherapists, approximately.

A matter of concern also to physicians is that when you set up a basic science board that board will be separate from your Board of Medical Examiners. A physician then transferring to another state will have more difficulty in transferring. We have, as you heard, in Minnesota a basic science board. The basic science board in Michigan will not recognize that board. Therefore, although a physician is qualified under the Minnesota medical licensing examination, he cannot get a license in Michigan until the Michigan basic science board will pass him, before he can be qualified even to take the examination or get an endorsement, which adds more difficulty to physicians transferring from state to state. Sometimes these boards become antagonistic to each other in various states, when it becomes quite a problem.

Gentlemen, I do not think the answer to your problem in this case is a basic science law. I feel that when you set up such a board then you open the way for every cult and every group to start hav-

ing pressure exerted to have an examiner on that basic science board take care of their people. (Applause)

... At this point Secretary Irving entered the room, and the delegates arose and applauded. ....

SPEAKER BAUER: We will interrupt the proceedings long enough for you to welcome our Secretary, whom we missed yesterday. We are glad he has recovered, and if I may speak allegorically we are glad his troubles are behind him. (Laughter)

Is there any further discussion?

DR. ARTHUR S. BROGA, *Madison*: When I was put on this Reference Committee I felt rather sorry for my colleague, Dr. Carroll. When he had to come in with this report, he rather expected tomatoes to be thrown at his head. Well, I have not so much hair on mine, so I would as soon have them thrown at me. Perhaps I had better explain why I put my name or signature to this report. I suppose all of us who affixed our John Hancocks to it had a lot of nerve, and we ought to have our pictures taken at least.

I gave this subject a good deal of consideration before I voted as I did. I have read all the reports on the subject that I could put my hands on. I have listened to Dr. Gullo and various members pro and con for a long time. Some of our own delegation are opposed to this measure, and some are for it, but as far as I am concerned the proof of the pudding is in the eating. I am meeting chiropractors up and down Main Street every day of the week and all over the rest of the town. The chiropractors are doing everything from seeing that my patients have their periods of time to that they get rid of so-called cancer of the stomach. For six years we have tried to put through a basic science law. For six years the law has been turned down. For six years the chiropractors have increased. Well, what are we going to do about it?

This basic science resolution does not give chiropractors a license. It is merely another hurdle. We have put a hurdle in by way of the primary school; we have put in the requirement of the grade school; we have put in the requirement of the high school; and we have put in the hurdle of the college. Now let us put in one more little hurdle, so that these gentlemen that go through high school and take a correspondence course from some school or other some place won't be able to set themselves up as chiropractors in this State.

Let me repeat again that this does not license the chiropractor; it merely puts in another hurdle. Eighteen states have passed basic science laws. In most of these states the chiropractors have decreased in number ever since. Therefore, that is why I voted for the resolution, and if anybody wants to throw any tomatoes at me I will be off the platform in a minute.

... The question was called for, and the motion was put to a vote, and was defeated. ....

SPEAKER BAUER: The recommendation of the Reference Committee, calling for the approval of the resolution, has been defeated.

*Section 81. (See 13, 76)*

**Report of Reference Committee on Constitution and Bylaws Amendments—Travel Expenses of Delegates to A.M.A.**

DR. FREDERIC W. HOLCOMB, *Ulster*: In regard to the proposed amendment to the Bylaws, Chapter X, Section 1, as changed by the suggestions of Dr. Rooney and Dr. Bedell, it will now read as follows:

"The Delegates to the American Medical As-

sociation who have attended each session of the House of Delegates of that Association, as certified by the Secretary of the American Medical Association to the Secretary of the Medical Society of the State of New York, shall be allowed traveling expenses."

I move the adoption of this amendment.

The motion was seconded, and as there was no discussion, it was put to a vote, and was unanimously carried.

### Section 82 (See 30, 43)

#### Lifting Resolution from the Table Regarding Enforcement of Medical Practice Act

**SPEAKER BAUER** Gentlemen, we have one resolution which was tabled until after the disposal of the Legislative Committee's report and the Reference Committee's report on the Basic Science Law.

**CHORUS** What resolution was that?

**SPEAKER BAUER** It was introduced by Dr. E. L. He Burdell, of Westchester County Medical Society, relative to the enforcement of the Medical Practice Act, the "resolved" clause of which reads

"Resolved, by the House of Delegates of the Medical Society of the State of New York that it be recommended to the Governor and the Legislature of the State of New York that the Medical Practice Act be more rigidly enforced in the interest of the health and welfare of the citizens of this State."

Then Dr. Werne moved an amendment that the services of our legal counsel be offered to the Governor. Dr. McCarty then moved a substitute motion that there be drawn up a proper chiropractic bill which would have our approval and would not lower standards. Then the matter was postponed until after these reports were disposed of. We should like to get this out of the way before proceeding with the other business. We have the original resolution as amended by the Reference Committee, then the amendment of Dr. Werne suggesting the services of our legal counsel be offered to the Governor.

**VOICE** Dr. McCarty's amendment has already been taken care of.

**SPEAKER BAUER** Yes. We will take up Dr. Werne's amendment first, which is that we offer the Governor our legal counsel.

**DR. JACOB WERNL** *Queens* Just one word in favor of that amendment. We have been passing resolutions to stop illegal practice, and if we don't indicate a path by which this enforcement may be accomplished we have not accomplished our purpose. The mechanism by which it will be accomplished or the amount of work involved I don't know, but I believe this Society should certainly offer the services of the legal counsel to the proper authorities, advising them how this law may be enforced.

**DR. JAMES F. ROONEY** *Albany* I hope that this amendment will not prevail. Our legal counsel has enough to do. His work is increasing all the time. We have already had two or three resolutions introduced here under one of which he will be obliged to go over all of the literature to be put out by certain of the committees as to their legal content, and what not.

There is no reason why this State Society should gratuitously say to the Governor "We are very glad indeed to have our legal counsel advise you. It is bringing coals to Newcastle. He has legal advisers of his own choice. In addition it would mean this—that any State action that were taken

on his recommendation would of necessity involve this Society because our Counsel would be tied to him. I hope it will not prevail.

**DR. WERNL** I withdraw the amendment.

**SPEAKER BAUER** Is there any objection to Dr. Werne's withdrawing the amendment?

There was no dissent expressed.

**SPEAKER BAUER** Hearing none the amendment is withdrawn.

Perhaps we should take some specific action on the substitute motion of Dr. McCarty that a proper chiropractic bill be drawn up.

**DR. ROONEY** I move it be disapproved.

**SPEAKER BAUER** That is not a proper motion. The thing to do is to vote the substitute motion down if you want to disapprove of it.

**DR. ROONEY** I move that it lie on the table.

**CHORUS** No.

The motion was seconded, and it was put to a vote, and was declared lost.

**SPEAKER BAUER** The motion to table is lost. The question now is on the adoption of Dr. McCarty's substitute motion. All those in favor of the substitute motion will say "Aye."

**DR. ARTHUR J. BEDDLE** *Albany* Before the question is finally put, I would like to have it read once more.

**SPEAKER BAUER** I have not the text of his motion noted down here, but as I recall it—and Dr. McCarty, correct me if I am wrong—the Legislative Committee was to draw up a chiropractic bill which the Medical Society could support, and which would not lower our present medical standards.

The question was called for and the substitute motion was declared lost.

**SPEAKER BAUER** You have now before you the original motion of the Reference Committee, which is that it be recommended to the Governor and the Legislature of the State of New York that the Medical Practice Act be more rigidly enforced, in the interest of the health and welfare of the citizens of this state.

The question was called for, and the motion was put to a vote and was adopted.

**SPEAKER BAUER** The motion is carried, and the resolution is adopted, as modified by the Reference Committee.

### Section 83

#### Announcements

**SPEAKER BAUER** The Council and the Board of Trustees will meet immediately after the general meeting this afternoon in Room 1321-A. That will be at approximately 4:30, I imagine.

Please be back here at 1:00 o'clock, and if you can get here a little earlier, do so, because to avoid a roll call we are going to have you checked in as we did last year and then checked as you vote. The first order of business this afternoon will be the elections.

### Section 84 (See 68)

#### Report of Reference Committee on New Business C—Publicity

**DR. J. STANLEY KENNEY** *New York* This resolution was introduced by Dr. Knickerbocker, of Ontario County, relative to publicity. I have consulted with him and with the Director of the Public Relations Bureau and in the interests of saving time I am going to read the resolution as it has been modified by your Reference Committee, with their

consent. This is the resolution in its amended form:

"WHEREAS, the practice of medicine is now, and in the future is likely to, in a greater degree, become a political football, to the detriment of the profession as a whole; and

"WHEREAS, a coordinated, uniform policy involving active participation of the county societies, to the limit of their abilities, to reach the public, within their individual areas, is highly desirable; and

"WHEREAS, the individual citizen is the final deciding factor and should be able to cast his vote with a reasonable degree of intelligence based on all information available; therefore be it

"Resolved, that a program aimed at reaching the public individually, in so far as possible, be instituted; and furthermore be it

"Resolved, that the responsibility for effective publication and/or distribution within its jurisdiction of the same shall be the duty and responsibility of each county society; and be it still further

"Resolved, that all expense incident to distributing effective publicity of such programs as shall be initiated by the State be paid by the State Society; and be it still further

"Resolved, that the trustees be requested to increase the appropriation for the Publicity Bureau to the extent necessary to meet additional demands for publicity that may be foreseen during the rest of the year 1944."

We recommend the adoption of the resolution in its amended form.

.... The motion was seconded. ....

SPEAKER BAUER: You have before you the recommendation of the Reference Committee approving the resolution as amended. Is there any discussion?

DR. ARTHUR J. BEDELL, *Albany*: I should like to vote against it, and ask your serious consideration of it. Do you think you are getting your money's worth out of the great sums spent on the publications that you receive, and are you prepared to spend more money for a similar purpose? Personally, I am not.

SPEAKER BAUER: Is there any further discussion?

DR. H. J. KNICKERBOCKER, *Ontario*: As I understand it, this resolution does not compel any appropriation. It simply asks for one, if necessary. The object of this resolution is to encourage the county societies to become more active in propaganda work. It was originally brought up in our county medical society that we were to take it up individually as a county medical society to counteract the Wagner bill. The Wagner bill apparently is not going to get anywhere this year, but there is going to be another one introduced next year. This resolution also can be used effectively to help sell your medical expense insurance. The individual voter is the one who will in the end determine what legislation you have, and if we do not stand in with the individual voter and the powers that be in our own localities, there is no chance, or mighty small chance, of our getting anywhere.

DR. JAMES F. ROONEY, *Albany*: I will propose an amendment to the report of the Reference Committee to the effect that the entire proposal of the approved resolution shall be referred to the Council, to be utilized at the discretion of the Council.

SPEAKER BAUER: Your motion is really to commit it to the Council rather than to amend it?

DR. ROONEY: Yes.

.... The motion was seconded, and as there was no discussion, it was put to a vote, and was carried. ...

SPEAKER BAUER: The resolution is committed to the Council.

### Section 85. (See 68)

#### Report of Reference Committee on New Business C—Change in Compensation Law

DR. J. STANLEY KENNEY, *New York*: Concerning the resolution introduced by Dr. Thomas M. D'Angelo, of Queens, concerning changes in the Compensation Law:

"WHEREAS, at the recent session of the Legislature of this State, the Workmen's Compensation Act was amended in such a manner as to divide the State of New York in this matter into two distinct portions, (1) the counties of New York, Kings, Bronx, and Queens, and (2) the remainder of the State; and

"WHEREAS, this change removes from the four metropolitan counties the power to rate physicians for compensation practice, approve and license compensation clinics, arbitrate disputed medical bills, and investigate and try physicians for certain violations of the Compensation Law; be it therefore

"Resolved, that the Medical Society of the State of New York petition the next Legislature and have legislation introduced to return to the four county medical societies those powers that were abrogated by the recent change in the Compensation Law."

Your Reference Committee is in complete accord with the purpose of this resolution and views with concern the division of the State of New York in the administration of workmen's compensation affairs as accomplished by the recently enacted legislation.

Since this Reference Committee's report has been embodied in the Reference Committee Report on Workmen's Compensation adopted by this House this morning. However, we feel that the importance of making every effort to regain the powers under the workmen's compensation laws that have been lost to the metropolitan New York counties should be urged and that this resolution should be sustained. We, therefore, recommend its approval and adoption.

.... The motion was seconded. ....

DR. JAMES F. ROONEY: I make a similar motion in respect to that resolution—namely, that it be committed to the Council.

.... The motion was seconded. ....

DR. JACOB WERNE, *Queens*: I don't think there is any question in the mind of any delegate here that a great injustice has been done to the metropolitan counties. If we feel that way, we should give the public evidence of our feeling and urge the action taken by Dr. Kenney. I am opposing the motion to commit it to the Council.

DR. ROONEY: I quite agree with you, but I think that continuing action will be secured by referring this matter as directed to the Council, which is the continuing House of Delegates, rather than to have it lie in a subcommittee until the next meeting of the House. That is my reason for referring it to the Council, so that action may be initiated immediately, and there may be the proper follow-through on it. I still hold to my motion.

.... The question was called, and the motion was

put to a vote, and the resolution was committed to the Council.

**SPEAKER BAUER** Does anyone else have a resolution to present?

There was no response.  
**SPEAKER BAUER** If not, we will stand in recess until 1 00 o'clock. Please be prompt.  
 The session recessed at 12 00 noon.

## Afternoon Session

Tuesday, May 9, 1941

The session convened at 1 00 P M

**SPEAKER BAUER** The House will be in order

### Section 86

#### Elections

**SPEAKER BAUER** The first order of business is the election of officers

#### TELLERS

**SPEAKER BAUER** The Chairman will appoint the following fifteen men as tellers

Charles F. McCarty, *Kings*, Chairman  
 Frederick W. Williams, *Bronx*  
 Wendell R. Ames, *Broome*  
 Harold F. R. Brown, *Erie*  
 Dominick F. Aloisio, *Herkimer*  
 Robert F. Barber, *Kings*  
 Charles Gullo, *Livingston*  
 Francis N. Kimball, *New York*  
 Edward C. Veprovsky, *Queens*  
 Laurence D. Redway, *Westchester*  
 Paul M. Wood, *New York* (Section on Anesthesia)  
 Joseph P. Henry, *Monroe*  
 Samuel M. Kaufman, *New York*  
 William F. Fyaz, *Oswego*  
 Mahlon C. Halleck, *Orlago*

They will report to Dr. McCarty, Chairman of the Board of Tellers

#### NOMINATIONS AND ROLL CALL

Nominations were then called for and received.  
 The Assistant Secretary called the roll and the following were accounted for

#### COUNTY SOCIETIES DELEGATES

<i>Albany</i>	<i>Chemung</i>

	Edward R. Cunniffe

## EX-PRESIDENTS

Martin B. Tinker	William D. Johnson
J. Richard Kevin	Chas. Gordon Heyd
Nathan B. Van Etten	Arthur J. Bedell
	James M. Flynn

## ELECTION OF OFFICERS, TRUSTEES, AND COUNCILORS

The following officers were elected:

President, Herbert H. Bauckus, *Buffalo*  
 President-Elect and  
 First Vice-President, Edward R. Cunniffe, *Bronx*  
 Second Vice-President, Scott Lord Smith, *Poughkeepsie*  
 Secretary, Peter Irving, *New York*  
 Assistant Secretary, Edward C. Podvin, *Bronx*  
 Treasurer, Kirby Dwight, *New York*  
 Assistant Treasurer, James R. Reuling, Jr., *Bayside*  
 Speaker, Louis H. Bauer, *Hempstead*  
 Vice-Speaker, William Hale, *Utica*

The following trustee was elected for a five-year term ending 1949:

William H. Ross, *Brentwood*

The following trustee was elected for a four-year term ending 1948; replacing Dr. Cunniffe, resigned:

Albert A. Gartner, *Buffalo*

The following Councilors were elected for a three-year term ending 1947:

Harry Aranow, *Bronx*  
 J. Stanley Kenney, *New York*  
 Floyd S. Winslow, *Rochester*

## ELECTION OF A.M.A. DELEGATES

The following were elected 1945-1946 delegates: Walter P. Anderton, *New York*; Albert F. R. Andresen, *Brooklyn*; Herbert H. Bauckus, *Buffalo*; Thomas M. Brennan, *Brooklyn*; Albert A. Gartner, *Buffalo*; William A. Krieger, *Poughkeepsie*; Oliver W. H. Mitchell, *Syracuse*; Edward C. Podvin, *Bronx*; James R. Reuling, Jr., *Bayside*; Floyd S. Winslow, *Rochester*.

The following were elected 1945-1946 alternate delegates: Clarence G. Bandler, *New York*; Emily D. Barringer, *New York*; Eugene H. Coon, *Hempstead*; Stephen H. Curtis, *Troy*; Andrew A. Eggston, *New York*; W. Guernsey Frey, Jr., *Forest Hills Gardens*; B. Wallace Hamilton, *New York*; Alfred M. Hellman, *New York*; Ralph Sheldon, *Lyons*; Denver M. Vickers, *Middletown*.

## ELECTION OF RETIRED MEMBERS

The following members were elected to Retired Membership:

Maurice C. Ashley, *Wappingers Falls*  
 Oliver L. Austin, *Tuckahoe*  
 Lemuel D. Ayers, *New Rochelle*  
 Amos T. Baker, *Briarcliff Manor*  
 Hiram R. Barringer, *Bay Shore*  
 John S. Black, *Scarsdale*  
 Gustave Brown, *New York*  
 George A. Clark, *Brooklyn*  
 Lewis G. Cole, *White Plains*  
 William L. Culbert, *New York*  
 John J. Davis, *Ozone Park*  
 Hughes Dayton, *Irrington*  
 T. Frederick Doescher, *Albany*  
 Alexander Goldman, *Bronx*  
 Charles Goodman, *New York*  
 Lawrence G. Hanley, *Buffalo*  
 Emilio L. Hergert, *Brooklyn*  
 Fred S. Hoffman, *Buffalo*  
 LeRoy F. Hollis, *Lacona*  
 Max Huhner, *New York*  
 Nathaniel H. Ives, *Mount Vernon*  
 Ulysses S. Kann, *New York*  
 Jacob E. Kaufmann, *New York*  
 George L. Laporte, *New York*  
 John E. Leonard, *Harford Mills*  
 Michael M. Lucid, *Syracuse*  
 Frederick W. Manly, *Phoenix*  
 William W. Meiners, *Malverne*  
 Milton P. Messinger, *Oakfield*  
 James L. New, *Lake Mahopac*  
 Ellwood Oliver, *Pine Plains*  
 Byron S. Price, *Port Chester*  
 Norman W. Price, *Niagara Falls*  
 J. Hubley Schall, *Brooklyn*  
 Cornelius J. Seay, *Scarsdale*  
 Burton T. Simpson, *Buffalo*  
 Jacob Sobel, *New York*  
 Frederic E. Sondern, *New York*  
 William H. Steers, *Brooklyn*  
 Guy H. Turrell, *Smithtown Branch*  
 Herman C. Wahlig, *Sea Cliff*

Section 87. (See 40, 64)

## Report of Reference Committee on Report of Council—Part II: Maternal and Child Welfare

SPEAKER BAUER: Dr. Donovan, as Chairman of the Reference Committee on Report of the Council, Part II, Maternal and Child Welfare, started to give you his report, and most of it was postponed until after some matters were taken care of. He will now proceed with his report.

DR. JOHN T. DONOVAN, *Erie*: Today I should like to finish my full report first, and not have you vote on each section separately in the first instance. There are six sections—that is true—but they are bound together, so why not vote on them at the

end of the report, or we will be here until tomorrow morning?

SPEAKER BAUER We will try it out that way, and as for the Reference Committee real-

fully that the existing law, but the Reference Committee feels that the various portions of the report should receive careful consideration and discussion by the House of Delegates.

1 The requirement that payment be made directly to the physician or the hospital rendering service

We agree with the view of the Council that this money should be paid directly to the servicemen's wives, thereby eliminating a third party in the relationship of physician to patient, and also discrediting any factor which might tend toward socializing medicine

2 The provision of hospital care at the "ward cost per patient day" to be determined by a pre-arranged formula

We agree with the opinion of the Council Committee, but feel it should be the privilege of the patient to be allowed to pay more for better accommodations if she so desires

3 Provisions for remuneration of physicians We agree with the Council Committee that the remuneration is low

4 The plan provides for additional fees where the services of a qualified consultant are required, but makes no provision for recognizing the extra services of a qualified obstetrician or pediatrician where such physician has undertaken the basic maternity or sick infant care of a patient under the plan

the extra services rendered

5 Fees paid under the plan must be the only compensation received for the services authorized under the plan

We agree with the Council's Committee that in view of the failure to have the available funds paid directly as a cash allotment an alternative would be to allow the funds available to be paid directly to the physician or hospital as complete or partial payment for the services rendered, in accordance with the patient's own arrangements with the physician and hospital

6 Initial plan that care given preceding date of authorization of the formal application for care could not be paid for under the plan

Your Reference Committee agrees and endorses the opinion of the Council Committee and the State Commissioner of Health in their objections to these limitations on the procedure

Under "Matters Now Pending"

1 The initial plan of the Children's Bureau urges the importance of infant health supervision, but in so doing provides that it must be rendered through approved child health conferences or well-baby clinics where they exist and are available without a so-called "means test" Where such are not available such supervision can be given under the plan only by a pediatrician or a physician meeting special qualifications in this field

We agree with the Council Committee and the State Commissioner of Health, who were thoroughly in accord with the inclusion of provisions for health supervision. They felt that the regulations were impractical and unreasonable in that they did not permit the patient the choice of a child-health conference or a private physician, nor did they make a reasonable provision for the general practitioner, who may deliver the baby and take care of it while it is sick but not supervise it while it is well

2 The Children's Bureau has interpreted the appropriation as intended to cover all medical care required by the expectant mother throughout her pregnancy and for six weeks thereafter

We agree with the Council Committee and the State Commissioner of Health and believe that this policy is unreasonable and will be changed in favor of a fairer definition of the types and extent of illnesses which the physician is called upon to care for under the fee for complete maternity care

3 Criticism by the practicing physicians of the various forms and statements which the State Department of Health has required in the operation of this plan

Your Committee understands that improvement has been made along these lines and earnestly requests that it continue to do so

I move the adoption of this portion of the Committee's report

The motion was seconded, and as there was no discussion, it was put to a vote, and was unanimously carried

DR DONOVAN On the resolution presented by Dr Charles Gullo, of Livingston County, reading

"WHEREAS, the present Federal Emergency Maternity and Infant Care Program of the Children's Bureau is intolerable, as it violates the physician and patient relationship, therefore be it

Resolved, That the Society of the to the American Medical Association, that it request the government of the Children's Bureau of Washington to alter the

because of the fact that this has been taken care of in our main report, we recommend no action on this resolution. I so move you

The motion was seconded, and as there was no discussion, it was put to a vote, and was unanimously carried

3 report your Refer as its very keen ap Jeffrey, Jr., and the their indefatigable emen's wives and of New York State, that regardless of legislation or fees the medical profession will assume care men dren of service-

Yo... ever M. Vickers, Joseph A. Geis, Louis A. Van Kleeck, Harvey B. Matthews, and John T. Donovan, Chairman, moves the adoption of this report as a whole

The motion was seconded, and as there was

no discussion, it was put to a vote, and was unanimously carried. . . .

*Section 88. (See 63)*

**Report of Reference Committee on New Business B—Workmen's Compensation, Deductions from Bills**

DR. ANDREW A. EGGSTON, *Westchester*: On the resolution presented by Dr. Abraham Koplowitz, of Kings, reading:

"WHEREAS, the practice of deducting 5 per cent from compensation bills which are paid within thirty days violates all business principles; and

"WHEREAS, the payment of bills is purely a business procedure; and

"WHEREAS, the usual business practice is the deduction of 2 per cent for the payment of bills within a stipulated reasonable period of time; therefore be it

"Resolved, that the Medical Society of the State of New York be requested to arrange with the Industrial Commissioner of the State of New York that no deduction be made in the payment of bills for workmen's compensation cases,"

your Reference Committee, New Business B, approves of this resolution, and moves its adoption.

. . . . The motion was seconded, and as there was no discussion, it was put to a vote, and was unanimously carried. . . .

*Section 89. (See 67)*

**Report of Reference Committee on New Business B—A Plan for Medical Care**

DR. ANDREW A. EGGSTON, *Westchester*: On the resolution introduced by Dr. Scott Lord Smith, of Dutchess County, reading:

"WHEREAS, the Medical Society of the County of Dutchess has approved in principle a plan to provide adequate medical care to that part of our population just above the line of indigency; and

"WHEREAS, the providing of medical care to this group is one of the vital problems of our day; and

"WHEREAS, the outline of this plan is attached to this resolution,"

(which I will not read at this time)

"Be it resolved, that the House of Delegates refer the Dutchess County Plan to an appropriate committee for further study,"

In reviewing the plan your Reference Committee finds it interesting and very comprehensive, and approves of the resolution. The Committee further recommends that the plan be referred to the Council of the Medical Society of the State of New York for further study.

Your Committee on New Business B moves the adoption of this resolution.

. . . . The motion was seconded, and as there was no discussion, it was put to a vote, and was unanimously carried. . . .

SPEAKER BAUER: Thank you, Dr. Eggston.

*Section 90*

**Presentation of Incoming President-Elect, Dr. Edward R. Cuniffe, to the House**

SPEAKER BAUER: One of the many pleasures of being the presiding officer is the fact that I have the

opportunity to be the first officially to congratulate the one who receives the honor of being elected President-Elect.

I note that the new President-Elect has just come into the House, and I will ask Dr. Van Etten to escort him to the platform.

. . . . Dr. Nathan B. Van Etten escorted Dr. Edward R. Cuniffe to the platform amid applause. .

SPEAKER BAUER: Gentlemen, your new President-Elect.

DR. CUNIFFE: Mr. Speaker and Members of the House of Delegates, I want to thank you very sincerely for electing me to this distinguished office of President-Elect, for I do consider it a great honor to be allowed the privilege of following in the footsteps of so many able men who have preceded me.

While I realize very well the dignity and the honor given this position, I am not at all unmindful of the responsibilities that go with it, and those responsibilities I will share with you, for I have in the past seen so many exhibitions of loyal, wise, intelligent co-operation from the members of this Society to their officers that I am led to believe they will not desert me.

If I can call upon you for help, because I know the wonderful material this Society contains, I am sure that I will not fail.

I am just reminded as I stand here that I feel a great deal like the story of Winston Churchill. When he was a boy in a public school in England, he won a prize for excellent work in one of his studies that he was pursuing.

He sent a letter to his mother apprising her of that fact, and she wrote back to him saying, "Winston, I am very glad to hear of your success. I know you don't deserve it, but try and live up to it." (Laughter)

I am very, very thankful of your confidence in electing me to this position and although I know I don't deserve it I will promise you that I will try to live up to it. (Applause)

*Section 91*

**Presentation of Incoming Second Vice-President, Dr. Scott Lord Smith, to the House**

SPEAKER BAUER: Dr. Sobel, will you present the new Second Vice-President to the House?

. . . . Dr. Aaron Sobel escorted Dr. Scott Lord Smith to the platform amid applause. . . .

SPEAKER BAUER: Gentlemen, your Second Vice-President!

DR. SMITH: Mr. Speaker and Members of the House, all I can say is that I appreciate very much the honor of being able to serve in what capacity I can, and particularly to participate in what must be the very interesting duties of conducting our very important Society in furthering the interest of Organized Medicine.

Thank you again! (Applause)

*Section 92*

**Report of Special Committee on Prize Essays**

SECRETARY IRVING: For the Committee on Special Prize Essays, Dr. Chas. Gordon Heyd has reported that two manuscripts were received, entitled (1) "Two-Time Charlie" and (2) "Sic Fatum Ordinum Est," for the Merritt H. Cash Prize; that both of these essays were considered by the independent reviewers as good papers but neither worthy of a special prize.

## Section 93

Postponement of Report of Subcommittee on Scientific Exhibit Awards of the Convention Committee

SECRETARY IRVING: For the Subcommittee on Scientific Exhibit Awards of the Convention Committee, Dr. Andresen has no report as yet to make, but it will be made and published in the JOURNAL in due course. (See June 15, 1914, issue, page 1326.)

Dr. Andresen asks the members of that Subcommittee who are present in the room to look him up after adjournment. The only two who are present are Dr. Walter G. Hayward, of Jamestown, and Dr. Nelson G. Russell, of Buffalo; Dr. Walter P. Anderton, of New York, is ill, as is Dr. William A. Groat, of Syracuse.

## Section 94

Vote of Thanks to Committees

SPEAKER BAUER: At this time the Chairman order for someone to reference Committees

Committee, and all the other Committees served to make this session a success.

Dr. CLARENCE G. BANDLER, New York: I so move.

SECRETARY IRVING: I second the motion.

SPEAKER BAUER: I am sure it requires no discussion, so I will put the vote. All in favor say "Aye," contrary, "No." It is unanimously carried.

## Section 95

Rising Vote of Thanks to the Speaker

Dr. DAN MELLEN, Oneida: I move that we give a rising vote of thanks to the Speaker for the work he has so ably done during this meeting of the House of Delegates.

... The motion was seconded, and was carried by the delegates arising and applauding. ...

SPEAKER BAUER: Thank you very much, gentlemen. I assure you it is always a pleasure to preside over this House. I have ever found it most cooperative in trying to make the work move along rapidly. I appreciate very much your new expression of confidence in me.

## Section 96

Suggestion to Use a Voting Machine in Future Years

At junty of New York, I should like to suggest that in future years a voting machine be used to count the ballots in this House. I hereby give notice of intention to amend the Bylaws to that effect.

SPEAKER BAUER: The notice will lie in the hands of the Secretary until next year.

Are there any other matters to come before this House?

... There was no response. ...

SPEAKER BAUER: All committees having reported, and there being no further business to come before this House, I declare the 138th Session of the House of Delegates of the Medical Society of the State of New York adjourned *sine die*.

(The session adjourned at 3:00 p.m.)

# Therapeutics

## CONFERENCES ON THERAPY

THESE are stenographic reports, slightly edited, of conferences by the members of the departments of pharmacology and of medicine of Cornell University Medical College and New York Hospital, with collaboration of other departments and institutions. The questions and discussions involve participation by members of the staff of the college and hospital, students, and visitors. The next report will appear in the August 1 issue and will concern "The Management of the Diseases of the Thyroid: III. Circulatory Disturbances."

### Management of Disorders of the Thyroid: II. Myxedema

DR. EUGENE F. DuBois: In the classical case of myxedema the diagnosis is very easy, and the treatment is relatively simple, but not all of the cases are classical. We may have various degrees of this condition, and underneath the picture of myxedema there may be concealed co-existing diseases and complications of the myxedema itself. It is well to remember that there are varieties of myxedema. The large majority of cases are due primarily to the failure of the thyroid function, but recently attention has been called to cases that are really Simmonds's disease, failure of the anterior lobe of the pituitary, and resembling myxedema or accompanied by myxedema. Attention has also been called to cases with a coexisting Addison's disease or an Addison's disease that is giving similar symptoms, and to other polyglandular conditions that are associated with myxedema.

We are having, I think, increasing amounts of man-made myxedema, made by surgeons, in operations for Graves' disease, taking out a bit more thyroid than they should. The condition is easily treated. There are cases of myxedema from a little too much x-ray therapy, and myxedema deliberately produced to relieve symptoms of coronary disease. Perhaps we are not having as many of those now as we did a few years ago. Then there are the recent drugs of the thio-urea series, such as thiouracil, that reduce thyroid function, drugs that give promise of being useful in the treatment of hyperthyroidism, and that can cause transient myxedema when used in excessive amounts. Just how many cases we will have of myxedema or hypothyroidism produced by these new drugs remains to be seen.

We must not forget the complications that may be concealed in the picture of myxedema, some of which are of prime importance, such as arteriosclerosis, the myxedema heart, and coronary disease, either manifest or latent.

The whole medical profession and a very considerable portion of the lay population of this country are indebted to Dr. David Marine for

the work he has done in the prevention and treatment of diseases of the thyroid gland. We are particularly fortunate in having him here today to speak on the physiologic aspects of myxedema.

DR. DAVID MARINE: I appreciate the honor of participating in what Dr. Shorr calls "the myxedema hour." However, I have to make some reservations. All of you know that new facts are hard to find and we all know that old facts are not always easily interpreted; at least, we do not always interpret them alike. I frankly confess to shortcomings in both categories.

One can classify the cases of myxedema into three general clinical groups: first, infantile myxedema (sporadic and endemic cretinism); second, adult myxedema (Gull's disease); and, third, experimental myxedema (cachexia thyreopriva). Of course, some sporadic cretins technically belong in the last category. They are due to congenital absence or congenital defects of the thyroid anlage.

Everyone is agreed, I think, that in myxedema the major feature is loss of function of the thyroid gland; in its simplest form, cachexia thyreopriva. There are, however, marked differences in the response to thyroidectomy due to age, sex, and species.

I shall now take up the groups in order. In cretinism and Gull's disease, the thyroid undergoes a slow, progressive, specific type of atrophy which is quite distinct morphologically from the type which follows hypophysectomy. I am sorry to say that at the present we have no knowledge as to why the thyroid undergoes this change. It has always been very difficult for me to understand why a tissue as resistant and as viable as the thyroid should undergo atrophy from intrinsic causes alone. Infections may destroy the thyroid, but infections account for only a few cases of sporadic cretinism. Infection as we ordinarily understand the word will not account for this particular type of thyroid change.

I have a section of a goiterous thyroid from a cretin calf in which one can still see evidence of

active hyperplasia, which is characteristic of the early stage and presumably is due solely to stimulation by the thyrotropic hormone. In the end or fibrotic stage of the process in a human endemic cretin there are scattered shrunken thyroid follicles with markedly distorted cells—some large and hyperchromatic others highly degenerated. One also may find, along with this destruction of the thyroid gland cells, mitotic figures which indicate an attempt to regenerate in spite of the destruction. This we call exhaustion atrophy.

The same type of change occurs in Gull's disease. In such a section the thyroid lobule may be in a state of advanced atrophy but one can still recognize the lobules and the glandular elements of the follicles. The lymphocytic infiltration about the follicles probably is an inflammatory reaction to the degenerating gland cells. Under higher magnification one finds degenerating cells with distorted hyperchromatic nuclei, sometimes along with mitotic figures just as in endemic cretinism. In other words, one sees a progressive destruction of the thyroid cells alongside of attempts to regenerate.

In contrast with the changes which one sees in myxedema and endemic cretinism, there is another type of change. I have a section of the thyroid of a dog which lived about eight months following hypophysectomy. Here there is nothing more than an extreme degree of involution. The cells are just vegetating, inactive, because there is nothing to stimulate them. The injection of thyrotropic hormone converts these flat endothelial like cells into cuboidal or even columnar forms. Thus then, is the difference between the involution of the thyroid follicle that follows withdrawal of the thyrotropic hormone (hypophysectomy) and the atrophy of the thyroid as seen in myxedema and in cretinism. In the latter, involution occurs in spite of increased amounts of thyrotropic hormone, there is both anatomic and chemical evidence that the hypophysis is producing an increased amount of thyrotropic hormone, which may lead to exhaustion atrophy.

Sections obtained in the early work of Lenhart and myself in Cleveland left a strong impression upon us, particularly one from a puppy, one of a litter of four cretin puppies with large goiters. This experience emphasizes the strong regenerative stimulus present in these cases. The puppy was so weak we could not do a biopsy at first, so we gave the animal some iodine and took a section about five days later. Despite the iodine there was considerable high follicular epithelium. The thyroid follicles were widely scattered in a myxomatous stroma. In another section of the same thyroid lobe two weeks later, the myxoma-

tous stroma was shrinking, i.e., the water was being removed and the follicles were coming closer together. They looked much more like normal thyroid follicles. At six weeks, the same lobe was practically a normal thyroid, and I might add that the animal grew to be a normal adult dog.

I mentioned the similarity between the anatomic changes that one sees in endemic cretinism and myxedema (Gull's disease). There also appears to be a relationship between Graves' and Gull's disease. The importance of Graves' disease as a precursor of Gull's disease was emphasized in the report of the British Myxedema Commission of 1888. Virchow, prior to that, pointed out that almost certainly there was some fundamental connection between Graves' disease and myxedema, but we all know that the pendulum has swung several times since those days. Now we are back again to the view that there is some connection between these two, although superficially they appear to be opposite pathologic processes. Graves' disease and Gull's disease have a somewhat similar geographic distribution. The highest incidence of Gull's disease occurs in those areas of the world where Graves' disease is most common, that is, in those countries bordering on the Baltic and North Seas and in our own country. There are more myxedema cases reported from northwestern Europe than in any other part of the world. In the great goiter districts of the world we have the other form—endemic cretinism.

There is about the same sex incidence in Graves' disease and myxedema. Perhaps myxedema is relatively more frequent in the female than is Graves' disease, in the latter it is something like five to one, depending upon the age and the location, and in myxedema it is probably between five and ten to one.

In endemic cretinism it is difficult to find any figures on the sex ratio, although the four or five series that have been reported indicate that it is slightly more common in the male. If there is any significance in this it is in the opposite direction of what one sees in Gull's disease.

Experimentally it is extremely easy to produce cretinism (infantile myxedema) in all the commonly available mammals by thyroidectomy alone during their infancy, and it is very difficult to produce myxedema in those same animals during the stage of active sexual life. Also, there are species differences. Herbivorous animals withstand thyroidectomy very well and carnivorous animals withstand thyroidectomy much more poorly. Among adult animals one gets a higher percentage of myxedema in the cat and dog than in the rabbit or sheep. The same age difference, in a general way, has been noted in human ca-

chexia strumipriva. Cachexia strumipriva is much more common in the young. Practically all the cases reported are in patients between the ages of 10 and 25 years. Horsley suggested that this age limitation might be related to cessation of growth.

T. Kocher and the Reverdin brothers noted that not all of the patients who underwent apparently total thyroidectomies developed cachexia strumipriva. Doubtless incomplete thyroidectomy or the presence of accessory thyroids would explain most failures, but there has always been difficulty in closely correlating the amount of thyroid removed with the symptoms produced. Similar observations have been made in recent years by Thompson and Thompson and others in association with subtotal thyroidectomy in the treatment of Graves' disease. One sees not infrequently a transient or even permanent myxedema following this operation.

There is the question whether patients with Graves' disease are not more susceptible to the development of myxedema, and acquire this state following the removal of less thyroid gland than is necessary to cause myxedema in individuals that do not have Graves' disease. Such a result could be predicted because Graves' disease is a natural precursor of Gull's disease. The metabolic rate may be minus 30 with or without myxedema. This all goes to show that the production of myxedema depends on more factors than merely a diminution in the amount of thyroid hormone.

Cretinism occurs in the first four years of life and before much sexual development has taken place, while Gull's disease occurs almost entirely during the decline of sexual life—the decline of sexual life in the female being due to one of many things (x-ray, radium, surgery, postpregnancy). Gull's disease in the male also occurs during the decline of sexual life.

It looks as if some glandular interrelations may be involved in promoting or inhibiting the onset of myxedema, such as the thyroid-gonad, the thyroid-hypophysis-gonad, and the thyroid-adrenal. I won't go into these because my time is nearly up.

I might just mention a few experiences which indicate these glandular interrelations in myxedema. We studied the urinary excretion of androgens in three cases of Gull's disease. We used the capon comb growth-promoting test. We examined a seventy-two-hour specimen of urine, although in such work a thirty-day specimen is preferable. I do not want to make too much of this test, but if carefully done I think it is superior to the colorimetric methods now available. A woman aged 50 was diagnosed as having Gull's disease by several competent internists. The basal metabolic rate was minus 23 and the

total androgen excretion during the three-day period, in 6,800 cc. of urine, was 0.86 mg., calculated as androsterone. Desiccated thyroid was then given, and in the course of ten days the dose was brought up to a grain daily. After ninety-three days another three-day specimen of urine (6,690 cc.) showed a marked increase in androgen excretion. It rose to 4 mg. and the basal metabolic rate rose to plus 14. Fifty-six days later a third specimen of urine (5,570 cc.) showed an output of 3.5 mg.

Another patient, a man aged 54, was observed at Mt. Sinai Hospital through the courtesy of Dr. B. S. Oppenheimer. The total excretion of androgens, determined in a similar manner, was 1.1 mg. before treatment, which is definitely below normal. After forty-seven days of treatment with desiccated thyroid ( $\frac{1}{2}$  grain daily) there was a significant rise in androgen excretion to 3.26 mg. and the basal metabolic rate rose from minus 22 to minus 4. Three cases are not enough from which to draw conclusions and more cases must be studied to see if this rise in androgen excretion regularly occurs. Dr. Rosen was unable to demonstrate any change in the estrogen excretion.

Where do the androgens come from in postmenopausal women? They could come from the adrenal cortex. We know that the functions of the thyroid and adrenal cortex are interrelated. There are numerous cases in the literature suggesting that the feeding of thyroid increases androgen production and excretion. A recent case reported by McCullagh from the Cleveland Clinic is strongly suggestive. A man aged 50 came to the clinic complaining of sexual impotency. After treatment with testosterone propionate he promptly regained sexual potency, but his metabolic rate remained minus 32. Desiccated thyroid was then substituted for the testosterone. The result was that his metabolic rate returned to normal and the sexual potency was maintained. Androgen excretion studies were not made in this case.

In closing, I might state that we are nowhere near a solution of the myxedema problem in spite of the fact that, as Dr. Shorr will tell you, we have nearly a 100 per cent satisfactory therapy in Gull's disease; and, in my opinion, a complete solution of the problem of myxedema cannot be expected until we have much more exact knowledge of the various endocrine interrelations than we now possess.

DR. DuBois: Dr. Shorr will speak on the general medical treatment.

DR. EPHRAIM SHORR: The broad background that Dr. Marine has given us of the pathophysiology of myxedema permits me to simplify my discussion. His remarks also demonstrate how

the possession of a successful therapeutic agent tends to oversimplify our concept of a clinical syndrome. It is becoming obvious that a condition such as myxedema cannot be localized to the thyroid apparatus alone.

Before passing to the treatment of myxedema it might be worth while to dwell on the problems presented by its diagnosis. As a clinical syndrome its manifestations are generally so clear-cut that one might anticipate no difficulty in recognizing it. For that reason it is disquieting to see how long a period generally elapses between the development of symptoms and their recognition by the practitioner. I have before me the charts of 9 cases which have been followed in the Outpatient Department. The duration of symptoms prior to recognition was as follows: fifteen years, ten years, seven years, six years, five years, four years, three years, one year, and three months. This is altogether too long and points to some sources of confusion which contribute to this lag.

Analyses of these cases have brought out some of the more common causes for this delay. Cardiac symptoms have often predominated and have led the physician to regard the phenomena to be on a purely cardiovascular basis. The pallor common to this condition has frequently led to a diagnosis of anemia, too often uncorroborated by actual laboratory tests, and to its treatment on this basis. The edema and anemia have in other cases prompted the diagnosis of Bright's disease. These appear to comprise the most common incorrect diagnoses. I do not mean to imply that all cases of myxedema are classical in their symptomatology and laboratory findings. Difficulties in establishing a diagnosis are occasionally encountered, but well recognized and reliable methods are available which in combination offer extremely reliable diagnostic criteria.

On the clinical side, there are generalized edema, changes in the skin and hair, sensitivity to cold, impairment of mental alertness, gain of weight, bradycardia, and lowering of the voice. On the laboratory side, the lowered basal metabolic rate and the elevated blood cholesterol values are most commonly employed as criteria. Circulatory studies yield valuable information in the form of changes in the size of the heart and in the electrocardiogram, the slower circulation time, and diminished minute volume. We have recently called attention to the value of studies of creatin metabolism in adult myxedema. The untreated case of myxedema will present entirely normal values for spontaneous creatin and creatin tolerance. Following the administration of thyroid, a temporary creatinuria and impairment of creatin tolerance occurs, thus, the

development of these abnormal creatin values after small doses of thyroid, as little as 30 mg daily of desiccated thyroid, is proving an unusually sensitive indicator of the existence of myxedema. In children, where the picture is frequently atypical, the determination of the bone age is of great help. The determination of serum organic iodine here is proving a valuable index of myxedema and, although at the moment more of academic than practical interest, the level of excretion of thyroid stimulating hormone from the anterior pituitary is generally elevated.

Once the diagnosis is made we must deal with the problems presented by the choice of therapeutic agent, the mode of administration, and the therapeutic goal. These may be best discussed by using specific cases as examples.

The case I have chosen is that of myxedema in a woman of 26. Her marriage at 18 was followed by four pregnancies in rapid succession, each pregnancy resulting in more and more evidence of myxedema until it finally became permanent. On admission her physical appearance was typical of myxedema. The thyroid was palpable and slightly enlarged.

Her basal metabolic rate lay between minus 30 per cent and minus 35 per cent. Her blood cholesterol was 430 mg per cent. Her nitrogen output in the urine was low, reflecting the lowered protein metabolism of this condition. Her circulation time was 14.6 seconds and her cardiac output 1.26 liters per square meter per minute. The surface area of the heart was 160 square cm. The electrocardiogram showed low QRS complex, low T wave, and a PR interval of 0.54 seconds. There was heart block and regular idioventricular rhythm. Her weight was 80 kilograms.

In most cases of myxedema the thyroid histology is virtually that of total atrophy, so that no significant restoration of function can follow the administration of iodine. Replacement therapy with thyroid hormone must be employed. In this case, because of the thyroid enlargement, iodine was tried for a period of twenty days, to ascertain whether there was sufficient residual thyroid tissue which might undergo involution and elaborate enough thyroid hormone to abolish the myxedema. This did not take place and replacement therapy was obviously necessary.

Of the available thyroid preparations, standardized desiccated thyroid is generally agreed upon as the preparation of choice. Thyroxin by mouth is unreliable in its action and there are very few indications for its intravenous use. Indeed, except under unusual circumstances, thyroxin has no place in the general therapy of myxedema. The advantages of standardized desiccated thyroid are its uniform action by mouth,

chexia strumipriva. Cachexia strumipriva is much more common in the young. Practically all the cases reported are in patients between the ages of 10 and 25 years. Horsley suggested that this age limitation might be related to cessation of growth.

T. Kocher and the Reverdin brothers noted that not all of the patients who underwent apparently total thyroidectomies developed cachexia strumipriva. Doubtless incomplete thyroidectomy or the presence of accessory thyroids would explain most failures, but there has always been difficulty in closely correlating the amount of thyroid removed with the symptoms produced. Similar observations have been made in recent years by Thompson and Thompson and others in association with subtotal thyroidectomy in the treatment of Graves' disease. One sees not infrequently a transient or even permanent myxedema following this operation.

There is the question whether patients with Graves' disease are not more susceptible to the development of myxedema, and acquire this state following the removal of less thyroid gland than is necessary to cause myxedema in individuals that do not have Graves' disease. Such a result could be predicted because Graves' disease is a natural precursor of Gull's disease. The metabolic rate may be minus 30 with or without myxedema. This all goes to show that the production of myxedema depends on more factors than merely a diminution in the amount of thyroid hormone.

Cretinism occurs in the first four years of life and before much sexual development has taken place, while Gull's disease occurs almost entirely during the decline of sexual life—the decline of sexual life in the female being due to one of many things (x-ray, radium, surgery, postpregnancy). Gull's disease in the male also occurs during the decline of sexual life.

It looks as if some glandular interrelations may be involved in promoting or inhibiting the onset of myxedema, such as the thyroid-gonad, the thyroid-hypophysis-gonad, and the thyroid-adrenal. I won't go into these because my time is nearly up.

I might just mention a few experiences which indicate these glandular interrelations in myxedema. We studied the urinary excretion of androgens in three cases of Gull's disease. We used the capon comb growth-promoting test. We examined a seventy-two-hour specimen of urine, although in such work a thirty-day specimen is preferable. I do not want to make too much of this test, but if carefully done I think it is superior to the colorimetric methods now available. A woman aged 50 was diagnosed as having Gull's disease by several competent internists. The basal metabolic rate was minus 23 and the

total androgen excretion during the three-day period, in 6,800 cc. of urine, was 0.86 mg., calculated as androsterone. Desiccated thyroid was then given, and in the course of ten days the dose was brought up to a grain daily. After ninety-three days another three-day specimen of urine (6,690 cc.) showed a marked increase in androgen excretion. It rose to 4 mg. and the basal metabolic rate rose to plus 14. Fifty-six days later a third specimen of urine (5,570 cc.) showed an output of 3.5 mg.

Another patient, a man aged 54, was observed at Mt. Sinai Hospital through the courtesy of Dr. B. S. Oppenheimer. The total excretion of androgens, determined in a similar manner, was 1.1 mg. before treatment, which is definitely below normal. After forty-seven days of treatment with desiccated thyroid ( $\frac{1}{2}$  grain daily) there was a significant rise in androgen excretion to 3.26 mg. and the basal metabolic rate rose from minus 22 to minus 4. Three cases are not enough from which to draw conclusions and more cases must be studied to see if this rise in androgen excretion regularly occurs. Dr. Rosen was unable to demonstrate any change in the estrogen excretion.

Where do the androgens come from in postmenopausal women? They could come from the adrenal cortex. We know that the functions of the thyroid and adrenal cortex are interrelated. There are numerous cases in the literature suggesting that the feeding of thyroid increases androgen production and excretion. A recent case reported by McCullagh from the Cleveland Clinic is strongly suggestive. A man aged 50 came to the clinic complaining of sexual impotency. After treatment with testosterone propionate he promptly regained sexual potency, but his metabolic rate remained minus 32. Desiccated thyroid was then substituted for the testosterone. The result was that his metabolic rate returned to normal and the sexual potency was maintained. Androgen excretion studies were not made in this case.

In closing, I might state that we are nowhere near a solution of the myxedema problem in spite of the fact that, as Dr. Shorr will tell you, we have nearly a 100 per cent satisfactory therapy in Gull's disease; and, in my opinion, a complete solution of the problem of myxedema cannot be expected until we have much more exact knowledge of the various endocrine interrelations than we now possess.

DR. DuBois: Dr. Shorr will speak on the general medical treatment.

DR. EPHRAIM SHORR: The broad background that Dr. Marine has given us of the pathophysiology of myxedema permits me to simplify my discussion. His remarks also demonstrate how

Zymenol provides a twofold natural approach to the two basic problems of Common Diarrhea;

**NORMAL INTESTINAL CONTENT REESTABLISHED**  
... through BREWERS YEAST ENZYMATIC ACTION\*

**NORMAL INTESTINAL MOTILITY RESTORED**  
... with COMPLETE NATURAL VITAMIN B COMPLEX\*

This twofold natural therapy assures normal bowel function without constipating astringents and absorptives, artificial bulkage or catharsis.

[Continued from page 1472]

As a rule, the amount of desiccated thyroid necessary for complete replacement in myxedema is relatively small. I have sampled at random a few of the patients who are being maintained at complete replacement levels to illustrate the usual range of dosage. These are the figures for the amount of desiccated thyroid taken daily: 180 mg., 150 mg., 120 mg., 120 mg., 120 mg., 90 mg., 90 mg., 75 mg., 60 mg., 60 mg., 60 mg. While it is a rule to which there must be an occasional exception, we have come to believe that whenever 180 mg. of desiccated thyroid given daily fail to relieve the signs and symptoms in a patient suspected of myxedema, some other cause must be suspected.

As regards postoperative myxedema and cretinism, the same diagnostic criteria and therapeutic regime should be employed as with Gull's disease. With the cretins, early diagnosis and treatment favor a restoration to normal well-being, but many residual defects may be anticipated.

DR. DuBois: Dr. Shorr, the doses mentioned refer to U.S.P. desiccated thyroid, do they not?

DR. SHORR: For the past twenty years we have used in this clinic one brand of thyroid preparation and have found it very uniform. It contains 0.2 per cent of iodine. In patients who have been carefully followed for four or five years it is quite amazing to see how constant its action is. I believe that everyone should work with one preparation to assure himself of its potency and get to know how to use it.

DR. DuBois: That is the lesson we learned in discussing digitalis. I think there has been a good deal of confusion in the literature of myxedema on account of the fact that some preparations of thyroid are very much weaker than the U.S.P. standard.

DR. HARRY GOLD: Would Dr. Shorr state why we don't use thyroxin more frequently, since it is a pure chemical?

DR. SHORR: Its action by mouth is much less regular, due to irregular absorption, contrasting with the regular effects obtained from the oral administration of desiccated thyroid. The necessity for intravenous medication is extremely rare.

DR. McKEEN CATTELL: Are the doses you employ sufficient to cover the theoretic total needs of thyroid hormone in completely deficient patients?

DR. SHORR: They are. The doses that I gave you will correct all the physiologic defects and bring about complete symptomatic relief. As I think Dr. Marine pointed out, you may see a few acini here and there which differ from those in normal glands in the absence of colloid, which in-

dicates that whatever is contributed by the gland must be slight. Would that be your feeling, Dr. Marine?

DR. MARINE: I would say that most patients with myxedema have some thyroid function, but it is negligible when they reach the state where the metabolic rate goes down to minus 30.

DR. SHORR: Should there be any uncertainty, I think it good practice to put such a patient on a course of iodine. If the symptoms and the physiologic abnormalities are not corrected, then it is certain that any residual function is negligible.

DR. MARINE: I might add that Osler has one of the best accounts of cretinism in America. He had a considerable number of patients treated with syrup of hydriodic acid alone and this remedy gave some relief of the symptoms and in several an increase in growth. One would have to infer from this that there was some thyroid present in clinical myxedema because in experimental animals we cannot get any effect from giving iodine if the animal has no thyroid tissue.

DR. DuBois: I might say that syrup of hydriodic acid is our favorite method of giving iodine on account of its relatively pleasant taste.

DR. GOLD: Do we recognize any hypothyroidism or myxedema with a normal basal metabolic rate? From time to time one encounters patients who have the clinical signs and symptoms of myxedema but turn out to have a normal metabolic rate.

DR. MARINE: That is a very difficult question.

I think that the metabolic rate does not depend on the thyroid alone. You can have a high rate after removal of much of the thyroid and there may be some thyroid insufficiency in relation to its influences on the function of other organs, not connected with the metabolic rate. We are getting into a theoretic question and we will have to leave it at that.

DR. GOLD: Is there any experience among the group here in the treatment of these cases?

DR. SHORR: Yes, I remember one such case. A woman in her thirties with a basal metabolic rate of about minus 5 had definite evidence of myxedema and on iodine showed no symptomatic change. Replacement therapy was instituted with considerable relief of symptoms. After about six months of such treatment, she ceased taking thyroid and has since been very well without replacement therapy. I think that fits in with Dr. Marine's conception of the picture of thyroid insufficiency with adequate metabolic rate but inadequate thyroid hormone formation for other functions.

DR. DuBois: I would like to add, though, a

[Continued on page 1476]

# BABY IS ONE YEAR OLD TODAY!

He has begun to take a wider variety of foods, but fundamental, as his "staff of life", is his daily milk quota.

Because of low curd tension, ease of digestion and palatability, he will delight in taking his milk ration in the form of Horlick's.

Horlick's prepared with milk is rich in muscle- and tissue-building proteins, as well as bone- and tooth-building calcium. Horlick's Fortified is reinforced with additional amounts of vitamins A, B<sub>1</sub>, D and G.

Obtainable at all drug-stores.

word of caution in the diagnosis of myxedema with normal metabolic rate. Of course, there is no one laboratory test that is diagnostic in all cases.

I might add a few words about the use of the basal metabolism in diagnosis and treatment. You must remember that a good many persons with metabolisms of minus 15 are within the normal range, and a few as low even as minus 20 are within the normal range. Statistically, however, the chances are that they are abnormal. You will see reports in the literature of large groups of cases with low metabolism, averaging around minus 20, that are labeled mild myxedema. Relatively few of these cases are reported from the clinics where they are making special studies of thyroid disease, relatively few from such places as Dr. Means' clinic in the Massachusetts General Hospital, or in the Mayo Clinic. A good many are reported by doctors who are enthusiastic over the results they obtain from thyroid medication. I think there are patients with myxedema in that range, and these usually have some of the classical symptoms of myxedema; they improve distinctly and satisfactorily with thyroid medication. However, there are a good many that are accused of having myxedema at that level but who do not have it. These are patients below par. They show fatigue. They are perhaps anemic. They tire easily. They have menstrual disturbances or sterility. Many of them improve with thyroid medication. Whether or not they have a real thyroid deficiency we are not quite sure, but undoubtedly the practitioner is labeling as having myxedema a great many patients who have never had it.

STUDENT: Does the dosage of thyroid vary with the activity of the individual? Would you use more thyroid material during periods of greatly increased exercise?

DR. DuBOIS: Would it be like insulin in that respect?

DR. SHORR: I do not think we have any methods sensitive enough to detect the small differences that might exist.

DR. JANET TRAVELL: Are there any other dangers connected with the use of thyroid in myxedema besides those which Dr. Shorr mentioned; that is, danger of precipitating myocardial failure or the anginal syndrome?

DR. SHORR: I might refer to the report by Means of two patients who, on thyroid replacement therapy, developed signs of acute adrenal insufficiency and had to be treated with large amounts of salt.

DR. DuBOIS: There is one more detail that Means brings out, the danger of the use of mor-

phine in myxedema. What should be the dosage of morphine in myxedema; none at all, or can you use it if it becomes necessary?

DR. SHORR: I would suggest its use with extreme caution.

STUDENT: Is the arteriosclerosis in typical hypothyroidism due to the thyroid disorder, or can it be explained by the age of the group?

DR. SHORR: The situation is too complex for us to be certain of the significance of arteriosclerotic changes. Long-standing myxedema occurring in the third decade, as in the patient I discussed, may be entirely free of arteriosclerotic changes.

DR. TRAVELL: If untoward results do not develop early in the course of treatment, are they apt to develop subsequently?

DR. SHORR: Yes. Cardiac symptoms may result from too sudden assumption of more work, quite apart from the existence of cardiovascular disease. There is, in addition, the patient in whom a greater cardiovascular load is imposed on a heart with coronary disease, and results in anginal symptoms.

DR. WALTER MODELL: I wonder whether there is an explanation for the tremendous resistance to the thyroid hormone which is exhibited by the patient with nephrosis to whom very large amounts of thyroxine have been administered intravenously without producing any appreciable effect.

DR. SHORR: There are undoubtedly great differences in sensitivity to thyroid exhibited by many normal individuals. We don't know the reason for the sensitivity of the patient with myxedema, and for the insensitivity of the normal individual and the patient with nephrosis.

DR. DuBOIS: I should like to say that the striking point brought out in regard to treatment is the need of great caution; that is, beginning it very gradually and watching the patient with extreme care. In planning the treatment of myxedema we should bear in mind the underlying pathologic physiology of the condition. Here is a person, usually a woman, who has been going around for months or perhaps years with a lowered metabolism; not only a lowered basal metabolism, although it is on the average 30 to 40 per cent below the standard, but also a lowered total metabolism. Such persons are not so active as most people. They try to keep quiet. As a result, the total metabolism has been lowered, and there has been a diminished demand on all of the functions of the body. The organs of the body have more or less adapted themselves to these lethargic conditions of the patient. When thyroxine was first discovered, they were tempted to use it dramatically in the treatment of myxedema, and even gave some cases the full therapeutic

[Continued on page 1478]

**Therapeutic Trojan Horse...** Sulfonamides are bacteriostatic; not bactericidal; not self-sterilizing. Thus a contaminated sulfonamide preparation, applied locally, may act as a therapeutic Trojan horse, releasing pathogenic bacteria inside the body's primary defenses.

Sulfathiadox\* Ointment, however, is self-sterilizing. This unique preparation contains microcrystalline sulfathiazole, 5%, with oxygen-liberating urea peroxide, 1%, and chlorobutanol, an antifungal preservative, 0.5%.

'Sulfathiadox' Ointment, recently developed by the Warner Institute for Therapeutic Research, is not only self-sterilizing with respect to *Streptococcus hemolyticus*, *Staphylococcus aureus*, and *Escherichia coli*, but also for the highly resistant,

spore-forming, anaerobic *Clostridium welchii* and *Clostridium tetani*.

The special water-washable, oil-in-water base of 'Sulfathiadox' Ointment assures better "point-of-contact" utilization of the sulfathiazole and is readily miscible with purulent and serous exudates. 'Sulfathiadox' Self-Sterilizing Sulfathiazole Ointment is supplied in 1-ounce tubes and in 1-pound jars... William R. Warner & Co., Inc., New York 11, N. Y.

[Continued from page 1478]

since gained a little weight. I saw her recently, about four years after the discovery of her myxedema, and she has gained possibly 10 pounds. She was a striking example of the thin myxedematous patient.

DR. DuBois: The classical patient with myxedema is said to have a gain in weight. Dr. William Plummer, of the Mayo Clinic, has made a careful analysis of the weights of his patients, 200 of them, and has found that the majority do show weights that are above the average, above the normal expectancy for height. About two-thirds of them have an increase in weight, but the average amount of edema in his patients is 13 pounds. If a patient has only gained 13 pounds in weight it does not mean anything added to the fat or muscles of the body. Thirty-eight per cent of his patients gave weights that were below the normal expectancy, and that means that they were below 13 pounds plus a loss in body tissues. By that I mean that if they were just at the normal weight, 13 pounds of edema was taking the place of 13 pounds of good normal tissue. In general, the severer cases were the ones that showed the loss in weight, and that points to an undernutrition of the whole body.

STUDENT: I should like to ask Dr. DuBois about the management of one of those patients with a minus 10 basic metabolic rate who does not have an obvious myxedema. Is there any indication for giving thyroid extract to such a person for a while? This is a person with fatigue and no obvious signs other than that.

DR. DuBois: A great many reports in the literature say they are getting excellent results, without any too much of a scientific background. There is a question as to what the thyroid medication is really doing. Just because they are going to the doctor they are paying more attention to their diet and they are being encouraged. Someone is taking an interest in their case. Their lives are better regulated. They are cheered up. There are a great many things besides the thyroid that go into that prescription.

DOCTOR: Is it conceivable that they might have a myxedema that is of lesser degree?

DR. DuBois: Yes, it is perfectly conceivable that their normal metabolism would be, say, plus 10, and they are running along 20 per cent lower than they should be. I think there are relatively few of those cases, and that the more careful the clinic the fewer you will find that are labeled myxedema. I don't see any harm, however, in trying thyroid medication for a short time.

DR. C. H. WHEELER: How about the case of the obese woman who is trying to reduce her weight and is found to have a basal metabolism

of minus 12 or 15, and who is given thyroid as an adjuvant to the dietary treatment? Is that to be recommended, do you think?

DR. DuBois: I think, if it is done very cautiously and carefully, thyroid is of use in obesity. It has to be watched. I don't think it should be a routine treatment.

DOCTOR: I should like to ask about the use of thyroid treatment in private practice where basal metabolism studies are not easily obtained; I mean practice that is not associated with clinics, large hospitals, and with poorer people. Is it feasible to carry people along with thyroid medication, using only clinical guides, after, let us say, an initial metabolism test?

DR. DuBois: It can be done by carefully watching the patient, using good clinical judgment. After all, you have to do that even if you do use basal metabolism tests. The final criterion is the condition of the patient and the judgment of the doctor. It can be done, and you have to do it.

DR. SHORR: Specificity of response is a very good indication of genuine myxedema because these patients respond very quickly, and in two or three weeks they are aware of a decided improvement in well-being. In borderline cases, however, and they are not uncommon—people who feel sluggish, who are tired and slow down toward the end of the day, and who frequently get a pickup in the afternoon if they have taken thyroid—I find myself unable to believe that the moderate improvement is very significant. The diagnosis in these cases is uncertain without laboratory data. Every patient with genuine myxedema develops a significant creatinuria after the administration of even a grain a day. There is always a fall in the cholesterol. With the cessation of treatment with thyroid in the true myxedematous patient there results a sharp rebound.

A great many workers feel that the rebound in cholesterol after cessation is even more significant than the change which occurs on administration of thyroid. The experience that we all have with people who feel better on thyroid, who get used to taking thyroid, who feel let down after stopping thyroid, and who can by every test be demonstrated not to have any thyroid insufficiency, shows the difficulty of solely subjective observations. Very often, as Dr. DuBois pointed out, ordinary hygienic measures, possibly some tea at 4:30, a sandwich and a cooky, will take that tired feeling away in a person who has resorted to thyroid for a long time.

DR. HARRY GOLD: How about a working rule for a course of treatment with thyroid material in the case of suspected hypothyroidism? You

## URINE-SUGAR TESTING with

# CLINITEST

(A Tablet Copper Reduction Method)

This refinement and adaptation of the copper reduction methods of Fehling and Benedict introduces several practical advantages for actual use.

### TWO MAJOR IMPROVEMENTS ARE:

*Elimination of external heat*—sufficient alkali is included so that all heat required for the test is self-generated within the test tube.

*Elimination of reagent-measuring*—amount accurately controlled by incorporation of standardized dry reagent mixture into Clinitest Tablet.

### SIMPLE, SPEEDY TECHNIC

Just drop a Clinitest Tablet into test tube containing proper amount of diluted urine. Allow for reaction—compare with color scale.

have a patient who, let us say, has symptoms suggesting myxedema, and either you cannot do a basal metabolism test or you find it near the border, minus 12. You decide to try thyroid. Would it do to proceed in this way: Give doses up to 3 grains a day, and if at the end of a week or two no distinct signs of improvement appear, one may then assume that it either is not a case of myxedema or that thyroid is not going to help? Would you agree to that as a working rule?

DR. SHORR: I think you can be reasonably sure of that. Our cases here with complete myxedema have required on an average 2 grains a day, and of the 20 or 30 cases that we have had under treatment none has required more than 3 grains.

DR. DuBOIS: Would not 3 grains be a pretty large dose? I should think it would be a better procedure to give 1 or 2 grains, and keep it up a month before you make your evaluation.

DR. GOLD: A month with a daily grain or two, and then if there is no response you are fairly sure it is not myxedema?

DR. SHORR: I think so.

DR. DuBOIS: Have you any figures on the strength of different preparations?

DR. GOLD: The U.S.P. preparations of thyroid are all assayed for their iodine content, and they are supposed to have a potency of approximately 2 mg. of iodine per Gm. of thyroid. Many people refer to the preparation as extract of thyroid. It is not an extract. It is just the gland, deprived of connective tissue and fat, dried, and powdered. In the older *Pharmacopoeias* it used to be called "dried thyroid." The newer revisions of the *Pharmacopoeia* do not label it "dried thyroid" but just "thyroid."

There have been some analyses of market preparations of thyroid. Preparations from different sources do not always produce equal effects in terms of their iodine content. Thompson (*J.A.M.A.*, 1935) and his coworkers reported that certain lots of beef and sheep thyroid produced less effect than hog thyroid in doses containing similar amounts of iodine. Lerman and Salter analyzed six preparations and found the iodine content to vary all the way from about 2 mg. to 4 mg. per Gm. of the dried gland. They examined those preparations further for the amount of thyroxine iodine, and found that this varied from 16 to 42 per cent. Examination of these specimens, however, in relation to their calorigenic action showed that they were not very far apart, which means that there are some factors relating to the potency of thyroid materials not directly explained by either the iodine or thyroxine content.

It is, perhaps, well to use thyroid material made by the same manufacturer, rather than to

shift from one to another, because in spite of the standardization by the iodine method there are differences in different thyroid materials which cannot be tested for at the present time. This will eliminate at least one source of variation.

There is just one other material which is used besides the thyroid itself, and that is thyroxine. I might call your attention to the fact that the *Pharmacopoeia* states the dose of thyroid as 60 mg. and of thyroxine as 0.5 mg. These are supposed to be equivalent. The dose of thyroid represents only 0.12 mg. of iodine, while of thyroxine, 0.32 mg. of iodine. This indicates that thyroxine iodine is not so effective in therapy as the iodine present in the original gland. This may in part be due to the fact that it is not so well absorbed from the gastrointestinal tract, which would be in line with what Dr. Shorr has said about thyroxine being irregular in its action and not so dependable as thyroid.

### Summary

DR. GOLD: The diagnosis of myxedema sometimes presents difficulties. It is to be distinguished from anterior pituitary disorders (Simmonds's disease) and Addison's disease. It is sometimes confused with primary heart disease, anemia, and Bright's disease. It may exist as a complication or an accompaniment of other diseases. There are substandard states of health associated with weakness and fatigue which are frequently treated as cases of myxedema because they present a slightly lower than the usual normal basal metabolic rate. There is considerable doubt whether thyroid medication produces any specific benefits in these cases and whether the reported benefits may not be the result of the other therapeutic measures usually applied at the same time.

Dr. Marine presented a very provocative discussion of the pathologic physiology of myxedema. He pointed out the difference between the thyroid gland after the removal of the pituitary and the thyroid gland in Gull's disease. In the former, the thyroid gland shows atrophy without signs of attempts at regeneration; in the latter, atrophy and regenerative hyperplasia may exist side by side. The thyrotropic hormone of the pituitary gland is active in Gull's disease and continues to stimulate the gland to activity, a fact which may lead to exhaustion atrophy. He indicated the glandular interrelations in myxedema by the example of the marked increase in urinary androgens during the administration of thyroid in patients with myxedema.

While most patients with myxedema have low basal metabolic rates, there are many patients with very low basal metabolic rates who do not

show signs of myxedema. There are some myxedema patients with normal basal metabolism values. Most patients with myxedema are overweight; some are underweight. This indicates the complexity of the problem of thyroid deficiency.

In the therapy of myxedema the object is primarily to restore the patient to a metabolic state most consistent with optimum health. Reversal of laboratory tests to normal such as the basal metabolic rate and the blood cholesterol usually accompany such restoration. There is some danger, however, in depending upon these alone, since hypothyroidism may serve as a protective mechanism in cases of advanced circulatory disease. Restoration of the metabolism to the average normal sometimes results in attacks of angina pectoris and overloading of the circulation with resulting heart failure. The patient's symptoms must, therefore, be used as a guide to the extent to which reversal of the myxedema state is to be carried. The therapy should be developed very slowly, over a period

of a few months, in order to enable the patient to make appropriate adjustments to the increase in metabolism.

The myxedema patient is very sensitive to thyroid medication and if a dose as large as 180 mg. daily fails to produce significant improvement, there is reason for doubting the accuracy of the diagnosis.

While there are occasional patients with Gull's disease in whom the residual active thyroid may be stimulated by iodine administration, thyroid material is the most important medication. The method of its administration was discussed. Thyroid material is preferable to the pure hormone thyroxin because it is apparently better absorbed and its action is therefore more regular and dependable.

It is well to confine one's practice to the use of one preparation of thyroid, because in spite of the standardization of U.S.P. thyroid preparation there are differences in the effects produced by thyroid preparations from different sources even when given in equivalent doses in terms of iodine.

#### SALIVARY AMYLASE AND DENTAL CARIES

A clear relationship between salivary amylase and the incidence of dental caries is reported by Turner and Crane<sup>1</sup> of the Forsyth Dental Infirmary, Radcliffe College. In order to establish this relationship, the rate of starch hydrolysis by saliva was determined under standard test conditions. In persons without dental caries this hydrolysis required approximately forty-five minutes for completion. The saliva of those with four to six cavities completed the hydrolysis within nineteen minutes, those with ten to twelve cavities within seven minutes, and those with twenty to thirty cavities in

less than two minutes. Without exception the rate of starch hydrolysis increased in direct parallelism with the number of cavities. Of 51 carefully studied cases not one was found in which the salivary starch-splitting rate was an exception to this rule. The origin and nature of this qualitatively or quantitatively increased buccal amylolytic enzyme is now under investigation.—*J.A.M.A.*, May 6, 1944

<sup>1</sup> Turner, N. C., and Crane, E. M.: *Science* 99: 262 (March 31) 1944.

#### AMERICAN CONGRESS OF PHYSICAL THERAPY TO MEET IN SEPTEMBER

The American Congress of Physical Therapy will hold its twenty-third annual scientific and clinical session September 6, 7, 8, and 9, inclusive, at the Hotel Statler, Cleveland, Ohio.

The annual instruction course will be held from 8:00-10:30 A.M., and from 1:00-2:00 P.M. during the days of September 6, 7, and 8.

The scientific and clinical sessions will be given

on the remaining portions of these days and evenings. All of these sessions will be open to the members of the regular medical profession and their qualified aids.

For information concerning the instruction course and program of the convention proper, address the American Congress of Physical Therapy, 30 North Michigan Avenue, Chicago 2, Illinois.

#### PENICILLIN AND GONORRHEA

The U.S. Public Health Service's Venereal Disease Research Laboratory, on Staten Island, New York, reports on treatment of sulfonamide-resistant gonorrhea with penicillin: seventy-six patients uncured by sulfonamides were given intramuscular injection of 10,000 units of penicillin every three hours, night and day, for forty-eight

hours. With one exception the group attained clinical and bacteriologic cures. The dose-time ratio employed was arbitrary.

Work now under way is directed toward determining maximum amount of drug and minimal period of treatment sufficient to produce a satisfactory cure rate.

## A LITTLE POWDER A LITTLE URINE

*Color reaction immediately, if  
... acetone or sugar is present.  
These two important short cuts  
simplify routine urinalysis!*

## Acetone Test (DENCO) AND Galatest

The same simple technique used in testing with Galatest (the dry reagent for the immediate detection of urine sugar) is also employed for the acetone test

Acetone Test (Denco) detects presence or absence of acetone in urine in one minute. Color reaction is identical to that found in violet ring tests. A trace of acetone turns the powder light lavender—larger amounts to dark purple.

A handy kit containing one vial of Acetone Test (Denco) and one vial of Galatest is now available. This is very convenient for the medical bag or for the diabetic patient. The kit also contains a medicine dropper and a Galatest color chart. This kit and refills of Acetone Test (Denco) and Galatest, are obtainable at all prescription pharmacies and surgical supply houses.

# RINGWORM INFECTION OF THE SCALP IN THE HARLEM AREA

## Discussion of the Present Inadequate Methods of Control

GERALD A. SPENCER, M.D., New York City

INASMUCH as ringworm infection of the scalp has taken on almost epidemic proportions in the Harlem area of New York City I feel that it is worth while to discuss some of the intricacies of the problem and to call attention to the inadequate measures thus far employed in its control.

Harlem is situated in the upper part of Manhattan and covers an area of approximately 3 square miles. Living there is a population of nearly 400,000 persons, 90 per cent of whom are Negroes. Up to the present time the medical authorities, both public and private, have watched with a peculiar indifference the infection of *tinea capitis* among the children of this area. There were no modern diagnostic facilities and no adequate methods for the treatment and control. Methods employed thus far consist in treating most cases of scaling and crusting of the head as ringworm and then applying one of the so-called fungicidal remedies. It is, however, gratifying to know that within recent months there has been established at the district health office of the Department of Health a filtered ultraviolet light for detecting infection of fungi in suspected scalp lesions of children.

### Incidence of the Disease

The incidence is much higher in boys than in girls. Several factors may be offered as an explanation. Boys play and romp more than girls.<sup>1</sup> They indulge in exchange of hats and caps more than girls do, especially the exchange of stocking caps, the wearing of which was the only preventive measure heretofore advised. They have shorter hair, a factor enabling the fungus to reach the base of the hair, where it develops and spreads. The length of the girls' hair and the fact that careful hairdressing styles consisting of curling, straightening with heated combs, washing, and braiding are popular are the factors that offer resistance to the growth of the fungi in the scalp of girls.

### Important Points for Consideration

There are two essential points that should be retained in the analysis of ringworm infection.

1. The causative agents of *tinea capitis* found in this area consist in most cases of two types. There is *Microsporon lanosum*, which is contracted from animals such as the kitten

and the pup. The other is *Microsporon audouini*, which is of human origin. *Microsporon audouini* infection, because of its resistance to therapy, is more often seen; hence its apparently higher incidence. The mycologic identification of the organisms is important not only from the diagnostic point of view but from the point of view of the prognosis and the treatment of the infection.

2. Ringworm infection of the scalp occurs in children under the age of puberty—namely, those under 12 years of age and in the elementary school. In infants it is not usually seen, not because of any natural immunity but because of the limited opportunities for them to be exposed to those infected with the disease.

[Continued on page 1488]

FIG. 1. Crusting lesions on scalp caused by staphylococci. No fungi were found.

<sup>1</sup> Lewis and Hopper; *An Introduction to Medical Mycology*, 1939; p. 45.

## *Vitamin D<sub>3</sub>* PLUS *A . . .* COMPLETELY MISCIBLE IN MILK

Desynon is synthetic vitamin D (the equivalent of vitamin D of animal origin) in pure crystalline form. Desynon with vitamin A is a preparation which disperses uniformly in milk. It is not oily and imparts no odor or taste to milk.

### *High Antirachitic Potency*

Desynon with Vitamin A contains 30,000 U.S.P. vitamin A units and 3000 U.S.P. vitamin D units per Gram . . . The special dropper supplied with each package delivers 500 vitamin A units and 50 vitamin D units per drop.

### *Dosage*

For prevention and cure of rickets, 10 drops daily incorporated in milk. In pregnancy and lactation and for conditions of disordered calcium and phosphorus metabolism, from 40 to 60 drops.

*Supplied in vials of 7.5 cc.*

## WINTHROP CHEMICAL COMPANY, INC.

NEW YORK 13, N. Y. *Pharmaceuticals of merit for the physician* WINDSOR, ONT.

[Continued from page 1486]

Control of the Infection

The diagnosis of tinea capitis should not be limited to clinical impressions which do not enable one to differentiate ringworm reaction of the scalp from that produced by any other pathogenic organism—as, for example, the staphylococcus (Fig. 1). Other methods are therefore necessary—especially the use of the Wood's filter illumination of filtered ultraviolet rays, under which the infected hairs show a characteristic fluorescent effect. By this method 20 to 40 children can be examined in an hour, and one cannot only detect carriers and contacts with newly infected hair, but can also use it as a means to control the success of treatment.

It is not sufficient to detect the presence of infection in the hairs. One should then determine by cultural and microscopic studies the type of organism, which is either *M. lanosum* or *M. audouini*. These organisms have distinctive characteristics that can be easily recognized under the microscope.

Treatment of tinea capitis consists in the use of topical applications in the form of wet dressings for the very acute phase, followed by salves

FIG. 2. Crusting lesions on scalp. *Microsporon lanosum* was the causative agent.

FIG. 3. Dry, scaly patch with alopecia. *Microsporon audouini* was the causative agent.

that are claimed to possess fungicidal powers, and roentgen therapy in sufficient and adequate doses to produce complete epilation. *Microsporon lanosum* infections are usually very acute, with production of oozing and weeping lesions (Fig. 2). This wet type responds favorably to topical remedies. Boric acid ointment is oftentimes sufficient to effect a cure. It is quite possible that the energetic allergic reaction of the scalp is the responsible factor in destroying the fungi rather than the topical remedies per se. On the other hand, *M. audouini* infection, most of the time, is dry and scaly; it stimulates hardly any inflammatory response of the scalp, and as a result seems to be deprived of the benefit of the desired allergic reaction (Fig. 3). In these cases x-ray therapy offers the best and quickest cure. In the hands of competent physicians trained in the use of superficial radiation, epilation can be accomplished in three to four weeks. However, it must be remembered that after the regrowth of hair following epilation, the child is by no means exempt from possibilities of reinfection. It then becomes a public health problem to eliminate early infected cases and control contacts and

They will destroy the zone of products made by the ethical industry and the products ad-

sizes will be needed this year, as purifiers are furnished almost every soldier and sailor serving overseas.

## IODINE...

*Simple; Rapid;  
Trustworthy*

The method of skin disinfection by Iodine is simple, rapid and trustworthy. It is suitable for emergency operations and for the treatment of infected surface wounds.

Iodine has withstood the test of time as a useful, powerful antiseptic. It does not interfere with phagocytosis and the growth of granulation tissue. Its action is sustained and its power of penetration is well established clinically.

known sources of infection, such as barber shops etc.

### Community Need

In the Harlem area of over a quarter of a million persons there are no adequate means for the control of ringworm infection among the school children. There is need therefore for:

1. An adequate center or centers for diagnosis by the use of filtered ultraviolet rays in all cases of crusting and scaling lesions of the scalp of children under the age of puberty.

2. Cultural studies to identify the type of organism in order that the best method of treatment based on the microscopic identification of the fungi may be determined.

3. Superficial x-ray unit to treat infections caused by *M. audouinii*.

4. More extensive education of persons and agencies in the community so as to have greater cooperation in combating the disease.

### Summary and Conclusion

Ringworm infection in the Harlem area seems to have taken on epidemic proportions.

Public and private agencies have not concerned themselves with the growing threat.

In this area of over a quarter of a million persons there is need for a center equipped with adequate diagnostic and treatment methods so as to control the infection.

2135 Seventh Avenue  
New York City

### NEW CANCER GROUP PLANS FUND DRIVE

Proper care for advanced cancer patients of moderate means is urged by Julius Jay Perlmutter, president of the newly formed National Foundation for the Care of Advanced Cancer Patients, with temporary headquarters at 450 Seventh Avenue, New York City. Speaking at a luncheon in the Hotel Pennsylvania at the first meeting of the organization since receipt of its charter on May 4, Mr. Perlmutter announced a campaign for \$1,820,000 as the immediate objective of the foundation. This sum, he explained, would provide 365,000 days of hospital care, based on \$5 a day for a private room for each of 1,000 patients. "Indigent cancer patients are comparatively well provided for today," Mr. Perlmutter said.

"Suitable places are needed particularly for the advanced cancer patients of moderate means. There is none so unfortunate as the cancer patient who can afford to pay \$10 or so a week. There is no place for him to go.

"Our ultimate aim is to provide a low-cost private room and bath for every such patient, to be referred to the foundation with as little red tape as possible by cancer physicians.

"The number of beds assigned to cancer patients in this area is 550. Of these, 80 per cent, or 450 beds, are exclusively for indigent patients. Twenty-one approved cancer clinics in the metropolitan area are caring for 15,000 cancer patients.

In 1943 there were 13,171 deaths resulting from cancer in New York City. With the increased number of deaths, and the facilities to take care of inoperable patients already woefully inadequate, future facilities will continue to be increasingly short of what is required."

Dr. Frank E. Adair, president of the American Society for the Control of Cancer and chairman of the cancer committee of the American College of Surgeons, pointed out that treatment of cancer patients was more costly than in other diseases because it involved radium, x-ray equipment, and surgery. Dr. R. R. Spencer, director of the National Cancer Institute of Bethesda, Md., agreed, putting the annual cost for a bed patient at \$342.

He commented that "no other disease comes near that" and added that, although cancer was second in the cause of deaths, it was first in importance from the economic standpoint. He described the new foundation as "one of the most significant health movements in a long time."

Officers elected included Mr. Perlmutter, president; Dr. Adair, vice-president and medical adviser; Mrs. Francis J. Rigney, commander of the Woman's Field Army of the New York Cancer Committee; and Morris W. Haft, vice-presidents; L. Morton Morrison, secretary; Morris M. Bernstein, treasurer; E. S. Tewksberry and Irving Kurcias, assistant treasurers.

### PEDIATRIC BOARD CHANGES EXAMINATION DATES

The American Board of Pediatrics announces that, because of the shortage of hotel space in New York, the dates for the fall examinations there have been changed. The amended schedule reads that the written examination for all candidates planning to take the fall oral examinations will be held on Friday, September 22. The oral examinations planned for St. Louis will be November 8-9 and New York

City December 15-16. Dr. C. Anderson Aldrich, Rochester, Minnesota, secretary of the board, again announces that group I, which requires that an applicant shall have been specialized in pediatrics for ten years or more, will be abolished on July 1. All applicants, regardless of qualifications, must take both the written and the oral examination.—*J.A.M.A., June 10, 1944*

# NEEDED AS NEVER BEFORE !

Many aged members of the medical profession, under the tension and strain of present war conditions, are in need of resources to help them meet their own daily life problems. The Physicians' Home is the answer. Will you lend a hand?

# Case Report

## BOTULISM: REPORT OF RECOVERY AFTER SERUM

WILLIAM L. MARSDEN, A.B., M.D., Brooklyn

MRS. A. C., aged 35 years, entered the hospital on the service of Doctors I. L. Cabot and A. T. Mays on April 24, 1944, with chief complaints of blurred vision, inability to swallow, inarticulate speech, and drowsiness, all progressively worse for forty hours.

Her husband stated that she had eaten one mouthful of home-canned string beans thirty-six hours prior to the onset of these symptoms. The beans had been prepared without pressure cooking, and the patient ate no more than one mouthful before realizing that they were spoiled. There was no nausea, vomiting, diarrhea, constipation, or other symptoms until forty hours before entering the hospital, at which time she felt drowsy, had some difficulty in swallowing, and noted a slight blurring of vision. Simultaneously, her family observed a change in her speech, characterized by a rasping quality, lisping, and slurring of syllables. Constipation developed and Epsom salts failed to produce a bowel movement.

The patient remained in bed, but grew steadily worse. The blurred vision became exceedingly marked, until she was unable to recognize persons or objects at a distance of nine or ten feet. Along with this she complained of "seeing double," and was unable to swallow solids or fluids. Just prior to admission to the ward her speech was completely inarticulate.

Throughout the entire course of the illness there was no pain, nausea, vomiting, diarrhea, melena, convulsive seizures, amnesia, mental symptoms, or loss of consciousness. The patient's past history, family history, and review of symptoms were essentially irrelevant.

### Physical Examination

The patient was a well-developed, well-nourished, white, adult woman, lying in bed and appearing gravely ill. She was drowsy but could be roused. Sensorium was entirely clear, and questions were answered intelligently by affirmative or negative head movements.

Marked bilateral blepharoptosis was the outstanding feature of the face. The eyes revealed small fixed pupils, lack of convergence, bilateral decrease in upward and downward movement of eyeballs, and bilateral sixth cranial nerve palsy, manifested by inability to rotate the eyes laterally past the midline. The fundi revealed no hemorrhages, exudate, vascular changes, or edema of the optic nerve head.

The oral mucosa was markedly dehydrated, not inflamed, and no gag reflex could be demonstrated. No evidence of vocal cord paralysis was found.

From the Medical Division, Methodist Hospital, Brooklyn.  
Resident in medicine, Methodist Hospital, Brooklyn.

Examination of heart and lungs revealed no abnormalities.

The abdomen exhibited moderate gaseous distention and bilaterally absent abdominal reflexes. However, faint peristaltic sounds could be heard, and there were no tenderness, spasm, organs, or masses palpable.

Pelvic and rectal examinations were not performed.

A complete neurologic examination showed hyperactivity of all superficial and deep reflexes of the extremities; absent abdominal reflexes; no Babinski, Oppenheim, Gordon, Hoffman, clonus, or other pathologic reflexes, and the sensations appeared normal. There was bilateral sixth cranial nerve paralysis, weakness of all extraocular muscles, fixed pupils, and blepharoptosis. However, the other cranial nerves appeared normal.

The clinical impression was of acute encephalitis, probably due to *Clostridium botulinum* toxin, on the basis of the history.

### Laboratory Data

The unused portion of beans was immediately sent to the laboratory, where a direct smear of the juice revealed gram-positive spore-bearing bacilli, morphologically identical with *C. botulinum*. Anaerobic culture, reported eighteen hours later, produced a gram-positive, spore-forming, gas-producing bacillus identical with *C. botulinum*.

Blood counts, urine, sedimentation rate, and blood chemistry were normal.

Lumbar puncture showed crystal-clear fluid under no increased pressure. The cell count, globulin, chlorides, Wassermann, colloidal gold, and sugar content were within normal limits.

The specimen of beans was sent to the New York City Department of Health Experimental Laboratories, where the following findings were made:

1. Injection of 0.5 cc. of a 1:1000 dilution of bacteria-free filtrate killed all inoculated mice in twelve hours.

2. Injection of 0.5 cc. of a 1:1000 dilution of the same filtrate failed to kill any mice of a group previously immunized with antitoxin serum type B, whereas all animals previously inoculated with type A serum died.

3. Injection of 0.5 cc. of a 1:1000 dilution of boiled bacteria-free filtrate failed to kill any injected mice.

These latter tests definitely confirmed the diagnosis of botulism due to *C. botulinum* type B.

### Treatment

A high colonic irrigation was given at once, with the expulsion of large amounts of flatus. Following

of distressing symptoms in

- CYSTITIS
- PYELONEPHRITIS
- PROSTATITIS
- URETHRITIS

**T**HE PROMPT symptomatic relief provided by Pyridium is extremely gratifying to the patient suffering with distressing urinary symptoms such as painful, urgent, and frequent urination, tenesmus, and irritation of the urogenital mucosa.

Gratifying also is the confidence in the physician and his therapy which is so evident in most patients who have experienced the prompt and effective symptomatic relief provided by Pyridium.

By its definite and established analgesic effect on the urogenital mucosa, Pyridium allays pain, and will frequently relax the sphincter mechanism of the bladder, which plays so large a part in the phenomenon of urinary retention.

**PYRIDIUM** is convenient to administer, and may be used safely throughout the course of cystitis, pyelonephritis, prostatitis, and urethritis. *The average oral dose is 2 tablets t.i.d.*

More than a decade of  
service in urogenital infections

[Continued from page 1492]

this, infusion of one liter of normal saline was started, on completion of the physical examination.

Upon identification of gram-positive, spore-forming bacilli in the direct smear, polyvalent anti-botulinum serum, types A and B, was obtained within one hour through cooperation of the New York City Department of Health and police emergency messenger. This was administered intravenously in doses of 10,000 units every four hours until a total dosage of 130,000 units had been given. At that point, clinical improvement merited cessation of serum administration.

Parenteral fluids and feeding through a Levin tube maintained general nutrition and body hydration. A daily dosage of 2 drams of cascara sagrada with 1 dram of mineral oil assured proper intestinal movements.

### Course in Hospital

During the first eighteen hours there was no change noted in the clinical appearance of the patient. However, after twenty-four hours she appeared somewhat less drowsy and was able to open her eyes wide without evident paralysis of the upper lids. There still persisted complete sixth cranial nerve palsy, and no improvement in speech or ability to swallow was noted.

After 70,000 units of serum (thirty hours) she was able to speak rather clearly, but in a faint whisper. Complete return of voice came about at the end of forty-eight hours of serum therapy, at which time she was sitting up in bed and able to swallow fluids in a normal fashion.

All evidence of extraocular palsy and all neurologic findings were completely absent at the end of the third day, and serum administration was concluded at that time after a total dosage of 130,000 units.

The patient noted a persistent weakness and lassitude, while constipation continued to be marked at that time.

On the fourth day there was a sudden rise in temperature to 103.6 F. along with a complaint of stabbing pain in the left side of the chest, most marked on deep inspiration. Examination revealed a faint friction rub with a few fine, crepitant rales in the ninth intercostal space posteriorly. A diagnosis of bronchopneumonia with pleurisy was made and sulfadiazine therapy was instituted. The temperature returned to normal in forty-eight hours and therapy was discontinued two days later.

The patient was allowed to sit up in a chair on the twelfth day in the hospital and was up and about two days later. She was discharged from the hospital on the seventeenth day to be followed by the outpatient clinic. At the time of discharge, the only complaints were a mild degree of weakness and some blurring of far vision.

### Summary

This was a case of botulism due to *C. botulinum* type B, as proved by bacteriologic and immunologic studies. The classic picture of this disease was evident, with a history of eating spoiled home-canned beans, later followed by extraocular palsies, blepharoptosis, blurring vision, diplopia, aphonia, dysphagia, and obstipation. Recovery was prompt and complete following administration of serum. Mild bronchopneumonia presented itself as a complication but was promptly controlled with sulfadiazine and the patient was discharged for home convalescence seventeen days after entering the hospital.

It is interesting to note that this was the first case of botulism reported within the confines of Greater New York since 1938.

## INTERNATIONAL COLLEGE OF SURGEONS TO MEET IN PHILADELPHIA

The Ninth Annual Assembly of the International College of Surgeons will be held on October 3, 4, and 5, 1944, at the Benjamin Franklin Hotel in Philadelphia, Pennsylvania.

The program will be devoted to war, rehabilitation, and civilian surgery.

This Assembly, sponsored by the United States Chapter, of which Dr. Thomas A. Shallow, F.A.C.S., F.I.C.S., of Philadelphia, is president, has set up its arrangement committee with Dr. Rudolph Jaeger as general chairman. Dr. Jaeger will be inducted as the incoming president of the United States Chapter at the Convocation on Wednesday, October 4. The new president came to the Jefferson Medical College from Denver, Colorado, where he specialized in neurosurgery.

Eminent surgeons in government, military, and

civilian practice have been invited to attend and present papers pertinent to surgery in their particular field of endeavor.

The chairmen of the various committees are: Dr. William Bates, president-elect of the Pennsylvania Medical Society, Program Committee; Dr. John Royal Moore, Philadelphia, Exhibits; Dr. Moses Behrend, Philadelphia, Publicity; Dr. Leonard D. Frescoln, Philadelphia, Hospital Clinics; Dr. William L. Martin, Philadelphia, Registration; Dr. Ernest F. Purcell, Trenton, N.J., Convocation; Dr. John E. Loftus, Philadelphia, Entertainment; Dr. Harold D. Corbusier, Plainfield, N.J., Rehabilitation; Dr. Benjamin Shuster, Philadelphia, Housing; Dr. William F. Whelan, Motion Pictures. The medical profession is invited to attend the Assembly and its sessions.

# ANNOUNCEMENT

## A NEW SERVICE...

In Hediger Hall, on the scenic Michell Farm grounds, we now have accommodations for a limited number of elderly ladies needing some supervision and medical care in a homelike atmosphere.

Information on request

Address: **MICHELL FARM**

106 North Glen Oak Ave., Peoria, Illinois

## IN THE INTEREST OF SCIENCE

*The American Weekly* (May 14, 1914) revealed an interesting story of a man who "died" four times for science.

Sir Joseph Barcroft, the Briton who gambled with the Grim Reaper for the good of medical science and his fellow men, has just received at the age of 71, a medal from the British Royal Society for his self-imposed brushes with oblivion.

As a young and inquisitive physiologist, Sir Joseph became convinced that the mind works best when the blood has a certain balance between its . . . . . ents And when this . . . . . the brain is affected.

. . . . . that low temperatures do something to the blood, so he removed most of his clothes and had himself shut up in a little room as cold as the Arctic. Only when his mind refused to function normally and he was, literally, almost frozen and unconscious did he signal for a rescue. In another experiment to test the effects of poisonous gases on the blood stream, he spent ten minutes with a dog in a chamber containing prussic acid fumes. The dog ceased to breathe long before Sir Joseph quit—with more valuable information for mankind.

In a third and very painful test of man's durability, he lived for a week in a sealed glass case from which life-giving oxygen was gradually removed. He found out what he wanted to know, but almost cut his career short accomplishing it. A fourth experiment included a twenty-minute sojourn in a carbon-monoxide filled room.

Commenting on his "journeys" that few have ever lived through to describe, Sir Joseph confirmed that freezing to death is one of the least painful ways to depart from this troubled world. "As I lay naked in that below-zero room," he reported, "I folded my arms and legs in an effort to protect myself from the painful cold. I couldn't think clearly as I lay shivering. Then came a beautiful, peaceful feeling of warmth. I stretched out my legs and, literally, basked in the bitterly frigid atmosphere."

## A New Hollywood

A moving picture of the birth of triplets was made in England.

As an aid to medical science, Mrs. Constance Hibbert of Snyderdale, England, consented to the photographing of her triple blessed event, which consisted of two girls and a boy. There were 20-minute intervals between births.

Jean, the first born, weighed five pounds; John, the second, weighed five and a quarter pounds. June, the third, weighed three and a half pounds.

What the picture may tell doctors that they do not already know is still unreported.

ian writes:

*Programs arranged by the Council Committee on Public Health and Education of the Medical Society of the State of New York are published in this section of the JOURNAL. The members of the committee are Oliver W. H. Mitchell, M.D., Chairman (428 Greenwood Place, Syracuse); George Baehr, M.D., and Charles D. Post, M.D.*

## Lectures on Penicillin Therapy at Westchester and Cattaraugus Meetings

THE Westchester County Medical Society met on June 20 at 9:00 P.M. at the New York Hospital, Westchester Division, in White Plains.

Dr. James E. McCormack, instructor in medicine at New York University College of Medicine in New York City, delivered a lecture entitled "Penicillin Therapy."

This instruction is provided jointly by the Medical Society of the State of New York and the New York State Department of Health.

The Cattaraugus County Medical Society re-

ceived postgraduate instruction in "Penicillin Therapy" on June 22 at 6:30 P.M. The meeting was held at the St. Bonaventure Golf Club in Allegany, New York.

Dr. William J. Orr, professor of pediatrics at the University of Buffalo School of Medicine, delivered the lecture.

This instruction was presented as a cooperative endeavor between the Medical Society of the State of New York and the New York State Department of Health.

## Instruction in Gynecology and Obstetrics in Ontario County

POSTGRADUATE instruction in obstetrics and gynecology has been arranged for the Ontario County Medical Society. The meeting is to be held on July 11 at 6:30 P.M. at the Geneva Country Club in Geneva.

The first lecture will be "Gynecology in General Practice." Dr. Nathan P. Sears, professor of gynecology at the Syracuse University College of Medicine, will speak.

The second lecture will be "Caudal Anesthesia in Obstetrics" by Dr. Francis R. Irving, professor of clinical obstetrics at Syracuse University College of Medicine, and Dr. Charles A. Lippincott, Fellow in Obstetrics at Syracuse University College of Medicine.

This instruction is presented as a cooperative endeavor by the Medical Society of the State of New York and the State Department of Health.

## PHYSICIAN POPULATION INCREASED BY 2,570 LAST YEAR

There were 5,952 additions to the medical profession in 1943, according to the data presented in the forty-second annual compilation of medical licensure and allied statistics by the Council on Medical Education and Hospitals of the American Medical Association and published in the *Journal of the Association* for May 13.

The report says that the number of physicians removed by death in 1943 was 3,382. "It would appear, therefore," the report says, "that the physician population in the United States last year was increased by 2,570. In view of the accelerated curriculum, with two classes graduating from most schools in 1943, one might expect that additions to the profession should be considerably higher. This, in reality, is the case at the present time. However, many physicians who obtained M.D. degrees in December of 1943 were not able to receive licenses until early in the year 1944, owing to administrative details. . . ."

"Estimated figures indicate that on February 1, 1944, the number of physicians in continental United States, including those licensed in 1943, was 186,496.

Excluding physicians who are in military service, engaged in full-time hospital work, retired,

not in practice, or engaged in full-time teaching, there remain about 100,000 physicians in private practice, some of whom are part-time teachers. . . ."

Throughout 1943, 8,392 graduates were examined for licensure, of whom 7,478 passed and 914 failed. Of 6,427 graduates of approved medical schools in the United States only 1.5 per cent failed. Of 76 graduates of approved Canadian schools, 15.7 per cent failed; of 101 who graduated from approved schools no longer operating, 5.0 per cent failed; of 1,031 graduates of faculties of medicine located in countries other than the United States and Canada, 49.8 per cent failed. There were 38.4 per cent failures among 757 graduates of unapproved schools.

Of particular interest is that portion of the report concerning licensure for relocated physicians. The report says that "Removal of physicians from civilian practice has resulted in a shortage . . . in critical areas, especially in some industrial and rural sections of the country. To assist physicians attempting to relocate in such areas, the licensing boards of fifteen states provide for the issuance of temporary permits or certificates to practice medicine. . . ." A total of 244 such temporary permits were granted by the fifteen states during 1943.

## LOUDEN-KNICKERBOCKER HALL, Inc.

81 LOUDEN AVENUE Tel. Amityville 53 AMITYVILLE, N. Y.

MRS. M. K. MANNING, Supt. TEL: Rockville Centre 3660

## IMPROVING PHARMACIST-DOCTOR TEAM

The American Pharmaceutical Association is encouraging colleges of pharmacy and medicine to cooperate in fostering a more effective understanding to smooth interprofessional relationship.

Such a program has already been undertaken by the Medical College of Virginia. How it works is briefly described by Harvey B. Haag, head of the Department of Pharmacology.

"The school of pharmacy here at the college," states Mr. Haag, "was asked some several years ago to aid in the teaching of prescription writing to our medical students. This cooperation was gladly given. At present during the regular pharmacology course eight lectures are given by Dr. T. D. Rowe and Dr. Karl Kaufman, in which the more common pitfalls and errors of prescription writing, as the pharmacist sees them, are brought to the attention of the medical students. In addition, other problems of mutual concern, such as, for instance, the intricacies of the narcotic laws, are discussed.

While this program has been in progress too short a time for final evaluation, it is already evident that the pharmacist is to continue to contribute to the betterment of the medical profession in the coming years.

## QUINIDINE UNDER STRICTER CONTROL

A WPB order published May 9, places Quinidine under more strict allocation.

Consumers are required now to present a doctor's prescription which must state that the quinidine is to be used for a cardiac disorder or "pursuant to WPB Order M-131."

The prescript . . . . .  
not be re-filled. A . . . . .  
dine certificate, . . . . .  
cate. Restrictions on quinine, cinchonine, cin-  
chonidine, and totaquine remain unchanged.

"HOW'S BUSINESS?"—A compilation of chain stores sales for March 1944 as compared with the same month in 1943, showed that of the twenty-nine leaders all but six showed substantial increases. Sears, Roebuck lead the 'eld with total sales of \$78,623,881 (over \$12,000,000 more than in March 1943); Montgomery Ward was second with \$53,382,733; Safeway Stores, third with almost \$48,000,000 in sales; J. C. Penney, fourth with over \$38,000,000; and Woolworth was fifth with over \$34,000,000.

In most instances total stores in operation showed a decrease. Among those reporting, Safeway Stores had 2,464 branches in operation, J. C. Penney had 1,609 and National Tea had 871.

## Superficialis

**SNORTS**—Blood donors are sure of a snort as a bracer after their donation at the College Point, Queens, blood bank. The local Kiwanis Club pledged a year's supply of liquor to the bank.

**WARNING**—A message from the Pacific front warned the girls at home to hang on to their men for between the Australian women and the Army Nurses they're going fast. According to Lt. Col. Jane Clement, director of 3,000 Army nurses in the southwest Pacific, an average of four nurses a day are being married to fighting men in that theatre

**RUM HOUNDS**—As reported to the American Psychiatric Association by Dr. Jules H. Masserman and his assistants of the University of Chicago, jittery cats are rum hounds. Healthy cats, given a chance to drink alcohol, refuse; but neurotic kitties prefer liquor. After the animals recover from their jitters they go on the wagon, permanently.

**STEAKS FROM CORN GERM**—Dr. H. H. Mitchell, protein expert of the University of Illinois, and other researchers have discovered that the corn germ comes up to beef in protein nourishment. They have further discovered that the oil in corn germ (which quickly becomes rancid) is often removed from corn products. Maybe our forebears had some reason, after all, for insisting that wheat and corn products should be ground not more than one week before consumption.

**SAUERKRAUT**—"You can have my share of sauerkraut," declares a news contributor, "However, I won't deny eating it is good for the health. One medical expert referred to it as 'the vacuum cleaner of the stomach.' Sauerkraut did not originate in Germany but in China. It was used by the Chinese to furnish the vitamins that are lacking in a rice diet.

## RAGWEED COMBINED

POLLEN ANTIGEN FOR FALL HAY-FEVER

**L**EDERLE has pioneered in the field of diagnostic and therapeutic hay-fever products for 30 years. An unsurpassed reputation has been earned in that time.

*Lederle* Diagnostics and Antigens, for hay-fever diagnosis and desensitization, possess the following outstanding qualities:

- The highly concentrated diagnostics give, with scratch technique, efficiency equal to that of intradermal testing;
- Uniform potency is assured by standardization according to the total nitrogen content;
- The buffered glycerine preservative protects the antigens from deterioration.

Many hay-fever sufferers experience aggravation of symptoms during the pollinating season because of house dust sensitivity. "HOUSE DUST EXTRACT *Lederle*" is available for diagnosis and desensitization.

*Don't Worry About It*

IN THE MANAGEMENT OF

CONSTITUTION

**I**N COLONIC STASIS putrefaction often induces systemic disturbances. In the atonic colon multiplication of putrefactive bacteria occurs, thus restoration of a normal aciduric flora is indicated to inhibit putrefaction.

For this purpose, implantation of the lactic acid producing acidophilus bacilli—indigenous to the intestinal tract—is logical corrective therapy.

Neo-Cultol<sup>™</sup>, a chocolate flavored mineral oil jelly containing *B. acidophilus* is pleasingly palatable and non-habit forming. It exerts a dual clinical effect . . . the antiputrefactive action of the *B. acidophilus* plus the mechanical action of the mineral oil.

**NEO-CULTOL**

# **Carnacton** OF CLINICAL VALUE

**In ANGINA PECTORIS • ARTERIOSCLEROSIS • PERIPHERAL VASCULAR DISEASES**

Carnacton is a biologically tested extract of highly vascularized and active diaphragmatic muscle with a high metabolic rate . . . providing dependable vasodilator and depressor benefits. Carnacton helps establish collateral circulation and promotes cardiovascular tone and vitality.

Ampuls of 1 cc. and 2 cc.—boxes of 12 and 50; vials of 30 cc. for oral use. For detailed brochure address Dept. N.

**CAVENDISH PHARMACEUTICAL CORP. , 25 West Broadway , New York**

# SOPRONOL *Inhibits* FUNGOUS INFECTIONS

**MONILIA**  
*albicans*

**EPIDERMOPHYTON**  
*inguinale*

**MICROSPORUM**  
*audouinii*

**TRICHOPHYTON**  
*purpureum*

... As demonstrated by clinical investigation  
in a leading United States hospital

In tests on a large number of hospital patients, Sopronol was found to exert an *inhibitory* rather than a destructive action on the fungus. The advantages of this method are obvious. Sopronol, taken readily into the fungous organism, prevents its development and spread. Hence the infection is quickly brought to an end, but without the customary skin irritation caused by poisonous by-products resulting from strong fungicides in contact with the mold. The chemical basis of Sopronol is sodium propionate.

## ALL SUPERFICIAL MYCOSES (RINGWORM)

Prescribe Sopronol for: Tinea Pedis, Tinea Cruris, Tinea Capitis, Tinea Glabrosa, due to "the dermatophytes"—Trichophyton, Epidermophyton, Microsporum, Monilia (Candida) and pathogenic aspergillae infections. Sopronol is non-irritating, non-keratolytic, non-toxic.

*Available in alcoholic solution, powder  
and water soluble ointment bases*

MYCOLOID LABORATORIES, INC., Little Falls, New Jersey

## GAME CALLED . . . PAIN

● Chalk up an error for the fielder, but don't call in a substitute when you want to provide real relief from the pain and swelling caused by the injury. Prompt application of Numotizine is of definite value in relieving pain and congestion from trauma, just as it is in controlling the symptoms of inflammation due to infection.

its established therapeutic actions:

1. Local and systemic analgesia.
2. Increased circulation in injured area.
3. Adsorption of exudates.
4. Decongestion and reduction of swelling.

Numotizine is supplied in 4-oz., 8-oz., 15-oz. and 30-oz. jars.

The effectiveness of

### NUMOTIZINE

in alleviating traumatic and inflammatory discomfort is based on

# YOU COMMAND... BREON COMPLIES!

You have demanded vigorous means of treating what is coming to be recognized as a distinct clinical entity—the results of deficiency of vitamin B complex. Not pellagra, nor sprue, nor beri-beri, yet, probably akin to all of them. For patients with this veiled and confusing disease, too often turned away as “neurasthenics”—here is—

## a new solution of liver and vitamin B complex

# BEXIVER

for intramuscular use when rapid, certain absorption of these factors in quantity is required. Bexiver is composed of crude liver solution to supply from a natural source both the known and unidentified constituents. It is fortified with the principal B complex vitamins—thiamine, riboflavin, and nicotinamide.

*In 10 cc rubber capped vials—boxes of 6 and 25*

## EPL Direct-recording Electrocardiograph\* ... giving instantaneous standard readings

- An inkless, direct writing recorder, designed and developed by the Electro-Physical Laboratories, Inc., after years of research and experimentation
- Completely eliminates all photographic procedures
- The cardiograph record appears instantaneously for interpretation at the bedside
- Ease of operation and simplicity of control assure good records with minimum effort
- Compact, light, portable; simple to handle
- Readings exactly resemble those of the best string type galvanometers
- Electrical interference does not affect record
- Because the record is immediately observable, a new field for cardiography in surgical procedure and pharmacological research becomes possible
- Operates from any 110-120 volt, 60 cycle, AC service
- High operating economy

FIGURE A—Photographic Method

FIGURE B—EPL Method

FIGURE C—Calibration

The exact similarity between the standard photographic cardiogram and the direct instantaneous cardiogram on this new EPL instrument is indicated in Figures A and B, which are records of the same subject taken a few minutes apart

**NOTE:** It has been determined by a series of measurements that cardiograms made on this instrument have no clinically detectable deviations from those made with the use of a high speed inertia less cathode ray oscilloscope

seeks advice on the*

## ADEQUACY

### OF INTERNAL MENSTRUAL PROTECTION...

Both in independent laboratory tests and in careful clinical studies, Tampax tampons have been shown to possess a wide margin of safety in providing for intravaginal absorption of the flux.

Though variations, of course, occur in the amount of blood lost during the period—most women have been found to conform within relatively narrow departures from the average of 50 cc.<sup>1</sup>

Even *Junior Tampax* provides amply adequate protection—with its absorptive capacity of 20 cc. for each tampon, or 200 cc. for the period (10 tampons are usually considered an ordinary month's supply). In addition, *Regular Tampax* has a capacity of 30 cc., and *Super Tampax* 45 cc. for each tampon (or 300-450 cc. for the period).

In a recent study<sup>2</sup> of 110 young nurses employing Tampax tampons for catamenial protection, it was found that

"95 per cent used tampons with satisfaction all through menstruation."

In another series<sup>3</sup>, 18 (or 90%) of 21 subjects had "complete protection". Also "complete protection was afforded in 68 (94%) of 72 periods reported."

Other clinicians<sup>4</sup>, investigating "twenty-five women under close institutional observation", noted that "with a tampon of proper size, absolute comfort and complete control of the flow can be obtained... the obvious advantage of the small, medium and large sized tampon of the particular brand (Tampax) is to be noted."

The results of this research parallel the experience of thousands of women who have found that Tampax affords thoroughly adequate protection.

One tablet chewed for one hour promptly initiates and maintains a high concentration of *locally active* sulfathiazole, averaging 70 mgm. percent saliva over the period of an hour's chewing. Two tablets increases the concentration approximately 20 percent.

# NEW, MORE EFFECTIVE METHOD OF TOPICAL CHEMOTHERAPY IN OROPHARYNGEAL INFECTIONS

**T**HE unique value of this new, effective method for the *local* treatment of certain throat infections consists in this:

1. Chewing one tablet provides a *high* salivary concentration (70 mg. per cent) of *dissolved* sulfathiazole...
2. that is *maintained* in immediate and *prolonged* contact with oropharyngeal areas which are not similarly reached by gargles or irrigations....
3. Chewing two tablets increases this concentration by 20 per cent...

4. with a relatively small ingestion of the drug, with either dosage, and consequent negligible systemic absorption.

Typical infections which have shown excellent response to treatment with White's Sulfathiazole Gum are acute tonsillitis and pharyngitis, septic sore throat, infectious gingivitis and stomatitis caused by sulfonamide-susceptible micro-organisms. Also indicated in the prevention of local infection secondary to oral and pharyngeal surgery.

Supplied in packages of 24 tablets, sanitaped in slip-sleeve prescription boxes—on prescription only. White Laboratories, Inc., Pharmaceutical Manufacturers, Newark 7, N. J.

# To the man who already is giving more

No group better appreciates the suffering of wounded men than members of the medical profession. That is one reason why physicians are putting double time and double effort into their work. Knowing that the best of medical care is only one of the urgencies of this crucial period in the war, physicians will be among the first to step up and double their War Bond purchases in the Fifth War Loan Drive. A word from the man who is already giving more will carry weight with others who may not be participating fully. Urge those you serve to double what they did before.

*Do More Than Before . . . Support the Fifth War Loan*

# KEEP THE CALCIUM BALANCE

## Positive

TODAY the availability of calcium-rich foods has been restricted by rationing and shortages. Ration points are needed to purchase certain dairy products rich in calcium while there is a scarcity of others. Hence it follows that in families where the calcium content of the diet was low even before the war, the present intake of calcium is now still lower

In such instances, prescribing a calcium-rich supplement, such as Dicalcium Phosphate Compound with Viosterol, is

more likely to secure patient cooperation than any admonishment to change the family food habits.

Tablets Dicalcium Phosphate Compound with Viosterol contain 9 grains dicalcium phosphate, 6 grains calcium gluconate and 660 U.S.P. units of Vitamin D to assure utilization of the minerals. The Tablets have a pleasant, candy-like, wintergreen flavor. During pregnancy and lactation the usual dose is one or two tablets, three times a day.

*The Tablets are supplied in boxes of 51 and 250.*

## PREDICTABLE RESULTS

THE ASTRONOMER can accurately predict, thousands upon thousands of years in advance, the path or position of every visible star and planet.

The physician can accurately predict the response in patients with uncomplicated pernicious anemia when Solutions Liver Extract, Lilly, are administered in regular and adequate doses. Predictable results are made

possible because each manufactured lot is clinically standardized on known cases of pernicious anemia in relapse.

In the average uncomplicated case, Solutions Liver Extract, Lilly, will produce a standard reticulocyte response and cause the red-blood-cell count to return to normal within a period of sixty days. Eli Lilly and Company, Indianapolis 6, Indiana, U.S.A.

### Continuous Medical Education

The problem of providing for continuous medical education in this nation has apparently reached an acute stage. It has been the subject of much study on the part of many agencies.

"In December, 1942, it was agreed by the Surgeons General of the Army and Navy and the directing board of the Procurement and Assignment Service that classes admitted to medical schools for the duration of the war should be made up of the following groups: Army Specialized Training Program students, 55 per cent; Navy V-12 students, 25 per cent; and civilian students 20 per cent, the latter group to be made up of women and men physically disqualified or otherwise ineligible for military service.

"The curtailment of the Army Specialized Training Program in April, 1944, provided that medical students and premedical students in the Army Specialized Training Program should continue in training but that no more students should be admitted to the program. . . ."

The curtailment of the A.S.T.P. program will, in fact, allow the filling of only 28 per cent of the places in the classes to be admitted to medical schools in 1945. The Navy will continue to fill 25 to 31 per cent of the places, according to the Directing Board, Procurement and Assignment Service

for Physicians, Dentists, Veterinarians, Sanitary Engineers, and Nurses.

"The condition seems to have reached a stalemate. Apparently the responsibility for action lies now with the Director of the Selective Service System, General Hershey. Several high officials of our government have indicated their complete sympathy with the necessity for maintaining continuity of medical education on a high standard. Apparently, however, the Secretary of War, Henry L. Stimson, and the Secretary of the Navy, James Forrestal, are not sympathetic to this need. They have said in a joint communication that the proposal to place premedical and premedical students on an inactive status in the enlisted reserve corps so that they may continue their studies would provide immunity from military service for five or more years to a selected group of young men. They suggest, moreover, that the essential in the selection would be the ability of the parents to finance the education, together with the ability of the student to complete the premedical or premedical courses and thereafter to qualify for entrance into approved medical or dental colleges.

"Apparently the Secretary of War and the Secretary of the Navy oppose granting deferment to premedical students, notwithstanding that failure to do so will lower tremendously the number of graduates in medicine and dentistry in the years 1948 and 1949. The opposition is based on the grounds that the armed forces need young men of intelligence with the proper physical qualifications

and that the immediate needs of the war for their services ought not to yield to the prospective use of these young men as doctors at a later date. They support this contention with the argument that may doctors now in the military service will be released by 1948."

The chronology of recent consideration of the problem is given below:

"The reduction in the Army Specialized Training Program had the effect of increasing the number of places which must be filled by civilian medical students by 27 per cent. This situation gave concern to the directing board of the Procurement and Assignment Service lest it be found impossible to secure an adequate number of properly qualified candidates for medical schools to fill the classes in the future and to keep the supply of doctors constant and adequate.

"Early in April Selective Service, after conference with the Inter-Agency Committee on Occupational Deferment, ruled that premedical students acceptable to the armed services, unless accepted for admission and matriculated and entered into actual classroom work in a recognized school of medicine on or before July 1, 1944, will no longer be deferred.

"The Procurement and Assignment Service wishes to record the following developments which have taken place since that time:

"At a joint meeting of the directing board of the Procurement and Assignment Service with the Surgeons General of the Army, Navy, and Public Health Service these problems were discussed, and it was mutually agreed that the effect of these two policies on medical education would be dangerous in terms of production of physicians, continued existence of the medical schools, and the effects on public health.

"On April 12, at the suggestion of the Procurement and Assignment Service, recommendations were made by Mr. Paul V. McNutt, chairman of the War Manpower Commission, to Maj. Gen. Lewis B. Hershey, director of Selective Service, embodying the objections and apprehensions of the Procurement and Assignment Service to this program.

"On April 15 a reply from General Hershey indicated that ' . . . No exceptions will be made as respects the date of July 1. We shall, as in the past, give full faith and credit to the certificates of professional colleges as to the status of students matriculated therein and engaged in actual classroom work within the school or under its immediate supervision. . . . '

"On April 26 a communication was forwarded by Mr. McNutt to the Secretary of War and to the Secretary of the Navy, urging the armed services to provide some status for a sufficient number of students to fill the entering classes in medical schools.

"On April 28 discussions were held by the directing board at one of its regular meetings with rep-

resentatives of the War Department, and these apprehensions were stated to them and discussed with them.

"On May 8 a discussion was held with Mr. James V. Byrnes, director of war mobilization, concerning this whole situation, and it was his opinion that since this matter under the law was entirely in the hands of Selective Service it was not within his province to take any action in this matter.

"On May 16 the Secretary of War and the Secretary of the Navy jointly advised the chairman of the War Manpower Commission that it seemed to them ' . . . that the immediate needs of the war for their (students') services ought not to yield to the prospective use of them as doctors in 1949 or thereafter, particularly when it is to be expected that the course of the war will by then make it possible to release many doctors at present in the military service. The action of the director of Selective Service in refusing these deferments was, therefore, in accord with the recommendations of the departments, and for them now to put these students into inactive reserve status would, in effect, be to defer them and to nullify the action of the director of Selective Service which we supported. . . . '

"This now brings the matter up to date, and in the accompanying table is submitted an estimate of what the status of medical classes will be under the program as it now exists.

#### "ESTIMATES OF MEDICAL STUDENTS FOR 1945

Total number of places in entering classes.....	6,440
Army students, 28 per cent.....	1,790
Navy students, 25 per cent.....	1,540
Balance to be filled by women and by men disqualified for general military service.....	3,110"

A proposal to supply qualified premedical students from men now in the armed forces who had previously been engaged in a course of premedical study and who, in addition, had already completed at least a year of military service does not seem to have a great deal to commend it except that it would be legally correct. It would, as pointed out in the *Journal of the American Medical Association*, involve picking out young men from remote areas and leave the selection of medical students to the Army. This does not seem to us to be desirable for many reasons, nor does it appear to us that the Army is particularly well qualified to fulfill this function. The *J.A.M.A.* rightly points out, editorially,

"About 3,500 doctors die each year in the United States. If the armed forces are to take 3,330 out of

6,440 in each medical class, leaving the balance of 3,110 to be filled by women and physically defective men, the situation five years from now will be hazardous. There will be an actual deficit of physicians coming into the profession each year. . . ."

Undoubtedly, some men will be released from the armed forces between now and 1949. How many and in what physical and emotional condition it is impossible to predict. In the same period of time many questions of vital importance will have to be answered.

"Where will our hospitals secure interns and residents? Where will the specialist branches in medicine secure the men who will be willing to undergo three to five years of additional training to qualify? Who will take care of the veterans in the greatly expanded medical care program of the Veterans Administration? Who will supply the needs of our allies and, particularly, the people of the liberated countries, where medical schools have been closed and physicians taken as prisoners to take care of the laborers from their own countries deported into Germany? What about the great program of extension of advanced medical education to our neighbors in South America? What about the tremendous needs of China for modern medical aid, which is so strongly emphasized by all of the leaders of our government? At a time when the whole world is confronted with a need for well-trained physicians as never before, American officialdom is apparently willing to cut off the supply at its very source."

Support for the suggestion that young men be returned as students who have had a year of military service is not lacking within the profession and in allied professions.

"The situation has been complicated by the fact that a committee representing the Council of the Association of American Medical Colleges and another representing the American Dental Association have agreed with the director of the Selective Service System that the taking of young men from the armed forces after they have completed at least a year of military service will be a satisfactory solution to the problem. From this agreement the Directing Board of the Procurement and Assignment Service, the Council on Medical Education and Hospitals, and many leaders in medical education strongly dissent. . . .

"The Council on Medical Education and Hospitals is convinced that the plan cannot insure an adequate supply of qualified medical students. The argument has been offered that the Selective Service System was able to carry out a similar program successfully for the supplying of coal miners

and copper miners. Any one familiar with the requirements in the field of premedical education will realize that there can be no analogy between these two situations. The continuing production of physicians of a high standard of education should have precedence because of the fundamental demand for such services at all times by the armed forces and because the needs of our civilian population now and in the future cannot be met by the education of men who are physically substandard and of women. It is, to say the least, uneconomical to spend the time, the effort, and the money necessary to put a boy through a premedical course, a medical course, and an internship when his physical condition is such as to indicate a lessened life expectancy and the possibility of invalidism in the future. Ten years of service to the people at the end of his career will be of far more value from every possible point of view than ten years at the beginning.

"Certainly this problem is one to which the House of Delegates of the American Medical Association should give most careful and serious consideration. . . .

"By June, 1944, young men now engaged in premedical education will begin to be inducted into the service. Letters pour into the headquarters office of the American Medical Association from leaders in education, from physicians and from citizens everywhere, urging that everything possible be done to halt this folly."

Halting "this folly" may not be a simple matter or even possible of accomplishment at all under the conditions prescribed by the Selective Service Law. France, in 1914, under its law requiring universal military service, was faced with a similar situation, and had to release many men from military service under circumstances far easier of accomplishment than these with which we would be confronted; with results in our recollection, which were far from satisfactory. Civilian medical care deteriorated then dangerously. Can we afford to have that happen here?

Some solution must necessarily be found which will not lower standards of acceptance for medical students nor create a group exempt from military service. In the present circumstances and under existing law the proposal of the director of the Selective Service System with the concurrence of a committee representing the Council of the Association of American Medical Colleges carries, of course, a good deal of weight without being necessarily the final word on the subject.

The House of Delegates of the A.M.A., at its session on June 12, 1944, adopted the following resolution:

"WHEREAS, the present policy of the Army and the Selective Service System in preventing the enrollment of a sufficient number of qualified medical students will inevitably result in an over-all shortage of qualified physicians with imminent

danger to the health and well-being of our citizens, therefore be it

"Resolved, that it is imperative that immediate action be taken by the President or the Congress of the United States to correct the current drastic regulations which result in a restriction of the number of students qualified to enter the courses of medical instruction in approved medical schools."

## Red Cell Reinfusion

Blood plasma is a vitally precious fluid these days. Not only is plasma used on a vast scale in military and civilian surgical and medical emergencies, but an additional demand on the available supply has been created by immunologists. Since it has been demonstrated that antibodies are most probably modified globulin,<sup>1</sup> it naturally follows that this globulin fraction of serum will be fractionated from adult plasma for prophylaxis or perhaps even treatment against certain contagions, such as measles, against which the great majority of adults are normally immune.

Such preparations of "immune adult globulin" have been successfully tested and are on the verge of widespread commercial preparation. They have the great advantage of concentration, which means much larger dosage per unit of volume, making for greater efficacy and ease of injection. This plasma extract, however, in turn creates another problem—how to increase the supply of plasma.

The factor limiting the frequency of blood donation is not regeneration of the lost serum protein but of the lost red blood cells. Deprivation of 500 cc. of blood entails a loss of 70–75 Gm. of hemoglobin, but of only about 17.5 Gm. of plasma protein. An interval of about eight to ten weeks between blood donations to permit adequate replacement of the lost hemoglobin is generally recommended by recent workers in this field.<sup>2</sup> The rapidity of the generation of serum protein is strikingly greater, for investigation has revealed a very high capacity of serum protein regeneration in a normal individual. The 17.5

Gm. of serum protein can normally be replaced in a matter of days rather than weeks.<sup>3</sup> Based upon these facts, the idea of reinfusing the usually discarded erythrocytes, with a valuable content of hemoglobin so difficult of replacement, came to a group of workers<sup>4</sup> as a solution to the bottleneck preventing frequent and repeated blood donations. Reinfusion, so employed within twenty-four to forty-eight hours, resulted in no anemia, no loss of blood volume, little decrease of serum protein, no alteration of the serum albumin-globulin ratio, no increase of bilirubin.

There was also no increase of reticulocytes and no evidence of red blood cell fragmentation.

No longer need the rate of hemoglobin regeneration serve as the criterion of frequency of plasma donation. The return of the plasma protein to the normal level should be the guide for determining the frequency of plasma donation, provided the separated red blood cells are reinfused into the donor. Further studies are in progress to confirm the laboratory and clinical features of this valuable innovation which will permit a much greater exploitation of the properties of human plasma without detriment to those who proffer full-sized and repeated donations of blood.

# NEPHROPTOSIS AND NEPHROPEXY

## A Critical Review of 55 Cases

CLARENCE G. BANDLER, M.D., F.A.C.S., BERNARD D. PINCK, M.D., and  
PHILIP R. ROEN, M.D., New York City

THE abnormally mobile kidney has been recognized as being productive of symptoms for many centuries, the earliest references to this condition having been found among the writings of Meuse, of Venice, in 1497. Other sporadic references were found subsequently, but it remained for Rayer's classic contribution in 1841 and Dietl's graphic description of symptomatology referable to this problem to focus attention upon the abnormally movable kidney as a relatively frequent occurrence. Surgical therapy was soon applied and we find that the first deliberate attempt at suspension of the kidney was done in Berlin in 1881 by Hahn.

In the western world Robert Weir, in 1882, was the first surgeon to perform such an operation. A wave of enthusiasm for this operative procedure followed during the next thirty years and because many of these operations were done almost as a fad, the diagnosis of nephroptosis and the operation of nephropexy fell into great disrepute. Thus, suspension of the kidney was within a short period highly acclaimed and abused. The discredit heaped upon nephropexy caused surgical neglect of many patients to whom such relief was necessary. It has only been within the last quarter of a century that the operation has been reevaluated and properly applied. The tendency at present is to regard nephropexy as a valuable tool in the armamentarium of the urologist, but to limit it to cases where definite indications exist for its use. By no means do all cases of excessive mobility of the kidney require renal elevation and fixation.

It is the purpose of this communication to review a series of 55 cases of nephroptosis treated surgically in the past decade at the New York Post-Graduate Hospital. It must be emphasized that many more cases of abnormally movable kidney than the number reviewed were seen, but the operation was limited to certain specific cases where certain criteria were satisfied.

### Definition

It must be borne in mind that the normal kidney has a range of motion of from 2 to 5 cm. on deep respiration and that in the thin individual the lower pole of the right kidney can generally

be palpated without great difficulty. The term movable kidney is here applied to renal mobility which exceeds the limits given above. A low kidney per se is not necessarily one which may be termed "abnormally mobile," for the displaced kidney may be associated with a generalized visceroptosis, and the low kidney is therefore not a specific single finding. A theory which has been propounded by a number of outstanding urologists and surgeons to explain the true excess mobility of the ptotic kidney is that there is a defect in the lower segment of the perirenal (Gerota's) fascia which permits the kidney to slip down when the individual is erect. This view would regard nephroptosis as a herniation of the kidney similar perhaps to the condition existing in the inguinal region where the viscera may descend through a defect in the abdominal wall.

The pathophysiology of the symptomatology in the syndrome of the ptosed kidney is dependent upon a number of factors which may operate individually or in combination:

1. The dislocated kidney causes tension upon and torsion of the renal pedicle, thus interfering with the normal blood flow through the kidney. This results in turgescence of the kidney, overdistension with blood, and increased intracapsular tension within the kidney, thus producing renal pain. This may be of such severity as to be termed renal colic, depending upon the rapidity of increase of the intracapsular distension and interference with the blood supply.

2. The sympathetic nervous system is affected by the constant pull and a situation of excessive sympathetic stimulation results. It is well known that the sympathetic nervous systems of the gastrointestinal tract, the ovary, and the uterus are intimately related to that of the ureter. This interrelationship may account for many of the more obscure abdominal and "neurasthenic" symptoms found in cases of nephroptosis. Moreover, the abnormally low kidney produces a direct pull upon the adrenal gland itself, producing changes within this gland and thus indirectly affecting the sympathetic nervous system and perhaps the hormonal balance.

3. The abnormally mobile kidney produces a constant drag on the intestines; barium studies show a definite sagging of the midportion of the duodenum where the right kidney is ptosed and the splenic flexure is similarly affected where the

left kidney is involved in the abnormal mobility. These effects are dependent upon the anatomic support of the kidney which is in part supplied by the peritoneal attachments and also the ligamentous bands to the duodenum, liver, pancreas, and spleen. It can readily be seen that gastrointestinal symptoms may therefore be a consequence of the nephroptosis.

4. Ureteral kink may be produced by the sagging of the kidney. This in itself is of no significance unless it causes obstruction to the urinary outflow with resultant caliectasis, pyelectasis, and hydronephrosis. Distension of the kidney produced in this fashion makes for increased intracapsular tension and the concomitant renal pain. To our way of thinking this factor is most important in the production of urinary tract pain; the stasis of urine induced by the obstruction predisposes to superimposition of infection and calculus formation. It is also our opinion that the demonstration of obstruction due to ureteral kink and the associated changes resulting from back pressure are positive indications for surgery though symptoms may be minimal. Such surgical therapy will often enable one to prevent progressive destruction of the kidney, which is bound to occur if the obstruction to urinary outflow from the pelvis is not overcome.

### Symptoms

These various factors are probably the basis for the differentiation of several groups of symptoms which are found as characteristic of the abnormally mobile kidney:

1. Symptoms referable to the urinary tract. These are most frequent. Pain may range from acute colic to constant nagging or dragging flank pain. Bladder symptoms may also be present and may include frequency, urgency, dysuria, and nocturia. Several of these symptoms, of course, may depend upon urinary infection, which is present in a considerable number of cases, stasis in the kidney acting as the underlying factor. A number of cases in our series also had calculus formation, and renal irritation due to presence of the calculus also contributed to the urinary symptoms.

2. Gastrointestinal symptoms are not infrequent. Nausea and vomiting with vague abdominal pains may lead to such operations as appendectomy or cholecystectomy to no avail in the relief of the patient's complaints.

3. Frequently associated with the above symptoms are such indeterminate "neurasthenic" complaints as fleeting aches and pains, nervousness, a feeling of ill-being, and similar indefinite statements which often make one regard the patient as a crank and an hypochondriac. Such

symptoms may be due to the sympathetic nervous system imbalance produced by pull of the displaced kidney.

### Analysis of Cases

This series comprises the 55 cases of nephroptosis seen at the New York Post-Graduate Hospital from 1933 to 1943 in which surgical suspension of the kidney was deemed warrantable. While many other cases of malposed kidneys were examined and treated, these did not meet the requisite specifications for operative intervention and are therefore excluded from consideration in this analysis. Appraisal is restricted rather to those patients whose histories and symptomatology demanded serious therapeutic effort.

Of the entire group upon whom surgery was performed, 42, or 67 per cent, were males. There was considerable variation in age range; with the single exception of a child of 4 who was operated upon, the age of the patients varied from 19 to 65. The largest fraction, however, 18 patients, were in the fourth decade of life. Twelve patients were in their twenties, while the age of 11 patients was between 40 and 50. These statistics correspond to the incidence reported in various studies from other hospitals throughout the world.

In 83 per cent of the cases renal displacement was on the right side and in only 13 per cent on the left. Bilateral involvement occurred in 2 cases.

The cardinal complaint of 54 patients was pain. One man who coincidentally had renal lithiasis was admitted to the hospital because of hematuria alone. The intensity of the pain varied from excruciating colic to moderate or dull ache. In 18 per cent the distress was described as severe intermittent attacks originating in the region of the costovertebral angle and radiating along the course of the ureter. Thirty per cent of the patients had lumbar pain of varying degree while 34 per cent complained of annoying, aching sensation confined to the flank. In the remaining cases the presenting symptoms were variable, ranging from perineal pain to epigastric distress, including low backache with upper and lower abdominal pain. Nausea and vomiting were included among the symptoms of 10 patients. Two of these had history of preceding appendectomy and four had been operated upon for gallbladder disease without alleviation of their ailments.

Hematuria was detected in five instances, in three of which associated lithiasis was established. The cause of bleeding in the other 2 cases was not discovered.

The occasional occurrence of bladder symptoms in the presence of renal ptosis is well known and

was part of the clinical picture of 20 per cent of our series. In all, frequency of micturition was the outstanding symptom with urgency being the next most evident complaint. Dysuria was present in 6 cases and nocturia in 2.

General toxemia of greater or less degree was a common finding, but only 6 per cent had chills and fever and 12 per cent had fever alone. Nervous excitability and mental tension were present in most cases.

There was considerable range in the duration of symptoms suffered by the patients before operation was performed. The shortest interval between the onset of illness and surgery in the entire group was two weeks, while the longest period of preoperative distress was twenty-four years. Within these limits there was wide variation. Careful survey indicates, however, that in 40 per cent symptoms were present from one to three years. Twenty-nine per cent were selected for operation less than twelve months after the initial observation of pain while 15 per cent had suffered for more than five years. In 22 per cent urologic intervention was precipitated by the appearance of signs referable to associated disease.

Urinalysis affords little assistance in establishing a diagnosis. Church states that albuminuria is almost a constant finding in renal ptosis. Of the 55 cases reviewed, pyuria was discovered in 43 per cent. Positive urine cultures were found after complete urologic investigation in 16 cases. Of these the right kidney alone accounted for 11, the left for 2, with bilateral involvement discovered in 3. Bacterial growth was discovered in the bladder urine of 12 patients. *Escherichia coli*, the most common offender, was isolated in 70 per cent of the infected cases, while *Staphylococcus albus* and nonhemolytic streptococci were cultured from a smaller number. In 5 per cent uncommon bacterial agents were found, these were *Bacillus pyocyaneus* and *B. proteus*. Twenty per cent of the involved cases had mixed infections. The statistics thus reported lend credence to the impression generally held that the

fixed or subsequent stasis, predisposes to infection of the urinary tract.

The most important feature of physical examination in the diagnosis of nephroptosis was found to be abdominal palpation. Palpable kidneys were discovered in 32 per cent of the cases, 25 per cent on the right side and 7 per cent on the left. Bilateral ptosis was revealed in 5 per cent of the entire series. Pain and tenderness either in the renal area or in the flank are of decided significance in establishing indication for surgical relief. These findings were present in varying degree in 29 patients. It is of interest to

note that in all instances where tender, palpable kidneys were manifested on physical examination, symptoms had been present for longer than two years.

As is indisputably recognized, the preoperative diagnosis of movable kidney or kidneys can only be made with absolute certainty by the use of excretory or retrograde pyelography involving exposures with the patient in the prone and erect or semierect positions. The radiographic findings in the current series are summarized in the accompanying table. Severe renal dislocation could be demonstrated in 38 per cent of the cases with moderate alteration in position in 62 per cent. It was possible to visualize roentgenographically ureteral tortuosity and kinks in 76 per cent of the patients examined (see Table 1).

TABLE 1

Side	Degree of Ptosis	Ureter Kink	Associated Stricture	Dilatation of Pelvis	Calyces
Right	54%	32%	66%	25%	62%
Left	8%	0%	10%	3%	2%

### Analysis of Pyelographic Studies

Structural as well as positional change in the ureter was revealed by the presence of stricture at the ureteropelvic junction in 28 per cent. Representing a manifestation of obstruction, pyelectasis was demonstrated in 67 per cent with further distention of the calyces in approximately half of these cases.

Nephroptosis with its variegated implications and predispositions engenders a number of associated renal diseases. In most instances, the precedence of excessive renal mobility to the allied kidney condition is clearly established, in other cases ptosis is first noted by the appearance of signs or symptoms referable to the complicating lesion. Associated renal disease of any sort was found in 67 per cent of the patients. Nephrolithiasis was diagnosed in 8 cases, in 3 of which ptosis was discovered only incidentally. In 14 per cent of the series, true hydronephrosis, as distinguished from the degree of dilatation signified by the terms pyelectasis and caliectasis, was demonstrated. The role of urinary infection in relation to the ptotic kidney has already been considered. Actual pyelonephritis, as demonstrated by morphologic alteration visualized in roentgenographic studies, occurred in 5 cases. In 28 per cent of the series, concurrent constriction at the ureteropelvic junction was recognized. Congenital anomalies were present in 4 cases.

### Methods

Though the various technics of suspending the

kidney differ, they have aims in common. Of necessity, each method of nephropexy must fix the kidney as high as possible, but at the same time must attain and maintain the normal relationship of ureter and kidney pelvis so as to facilitate drainage. In other words, not only is anatomic reposition essential, but normal physiologic function is a prime requisite. Moreover, any such method must not be so technical as to preclude its widespread use, nor must it produce damage to the renal substance. The numbers and types of nephropexy are legion; we hold no particular brief for any particular procedure but it is obvious that the most simple operation which attains the above objects is to be preferred. Different methods have been employed by individual surgeons in the cases described in this communication, but we ourselves use a method which has been adequately presented and illustrated by Woodruff. This, in essence, consists of denuding a portion of the posterior surface of the kidney of its capsule and approximating this area to the under surface of the lowermost ribs. Suture of the perirenal fascia and fat to the lumbar muscles below the kidney is also performed, as suggested by Deming.

If is, of course, well known that widespread and tenacious adhesions are found in reoperating on a kidney which has previously been surgically exposed. It would appear then that sufficiently dense adhesions will form to keep the kidney suspended no matter what method of nephropexy is employed, just so long as the technic fixes the kidney in its high position long enough to permit the formation of these adhesions.

It should be apparent from this that failures in surgical treatment of nephroptosis are generally *not* due to faulty surgery and poor technical procedure, but are due rather to the lack of recognition of associated pathologic lesions which demand correction, or to the improper choice of cases. As we have seen, the abnormally mobile kidney is frequently attended by concomitant pathologic lesions, particularly at the ureteropelvic junction; any procedure which aims merely at pegging this kidney will of course be followed by inevitable failure, for correction of the accompanying lesion is a *sine qua non* of success. In fact, in many cases without any symptoms at all, an unusual degree of renal mobility is found, yet the kidney empties normally. Thus where symptoms do exist with a ptotic kidney, exhaustive search must be made for the presence of accompanying lesions if the corrective surgery is to have any measure of success.

Adequate follow-up studies were carried out in 40 patients of whom 27 acknowledged subjective cure by the operation (see Table 2). Seven patients stated that, while some symptoms were

TABLE 2.—ANALYSIS OF END RESULTS

Side	Cases Followed	Complete Relief of Symptoms	Persistent Symptoms		X-Ray Findings Dilatation or Kink	X-Ray Findings	
			Severe	Mild		Good Position	Bad Position
Right	34	70%	15%	15%	8	22	3
Left	6	50%	12%	33%	1	4	1

either constantly or intermittently present, their general condition indicated improvement over the preoperative status. In one unusual case nephropexy effected alleviation of contralateral pain. In 15 per cent of the followed cases unsatisfactory results were obtained. Interview with these patients revealed that symptomatic relief of preoperative complaints, if at all noted, was transient and that surgery had afforded no significant amelioration of subjective distress. In one instance subsequent nephrectomy was necessary. Roentgenographic follow-up was accomplished in 30 cases. Of these, pyelography revealed anatomic correction in 26 with renal malposition persisting in 4 cases. Pelvic or calyceal dilatation or ureteral kink was demonstrated as persisting postoperatively in 9 cases.

### Comment

Survey of 55 cases of nephroptosis deemed suitable for surgical suspension has brought to our attention certain specific deductions:

1. Operation solely for the purpose of correcting excessive renal mobility in the absence of symptoms or stasis is not warranted.
2. The performance of nephropexy *per se* without correction of concomitant renal or ureteropelvic lesions is doomed to failure. As a corollary to this consideration, it must be emphasized that search for associated disease of the kidney or ureteropelvic junction must not be neglected even where simple ptosis appears to reveal the clinical picture by itself.
3. A properly performed nephropexy not only demands suspension in a high position but also requires fixation so that the proper renal axis is achieved. This is obviously necessary for adequate drainage of the kidney pelvis.
4. For final estimation of ultimate result, *urographic evidence*, in addition to subjective improvement, must be weighed.
5. While the efficacy of nephropexy as a tool in the armamentarium of the urologic surgeon is not to be minimized, indiscriminate employment of this procedure on all palpable kidneys is ill-advised.

From the above considerations it is possible to evolve a set of criteria establishing specific

indications for fixation of the kidney. In the interpretation of cases suitable for nephropexy where a careful history, physical examination, and urologic study have been made, emphasis must be placed on the following facts:

1. It must be definitely established that symptoms are referable to the urinary tract. Investigation of nonurinary symptoms such as gastrointestinal distress must be complete before such symptoms are attributed to the abnormally mobile kidney.

2. Excessive renal mobility must be demonstrated by urographic procedures in both the erect and recumbent posture. The descent of the kidney in the upright position must exceed those limits generally regarded as normal, since a certain minimal mobility is usual anatomically. Serial pyelography as advocated by Henline affords corroboratory evidence, but is by no means essential to the diagnosis.

3. Simulation of pain by overdistention of the pelvis on the affected side through retrograde catheterization is a helpful but by no means essential diagnostic criterion. Renal displacement, despite the absence of evidence of constant obstruction to urinary outflow, may require fixation of the kidney because of frequency and severity of pain, as occurs in repeated Dietl's crises.

4. Where infection is present and yet no stasis can be demonstrated conservative measures directed at the infection should be attempted first.

5. On the other hand, where stasis and obstruction to the urinary outflow are definite, such findings in addition to the ptosis would appear to make the surgical procedure even more imperative.

6. Any attempt at the conservative dismissal of the ptotic kidney presenting definite symptoms and obstructive urinary changes by the use of so called ptosis belts and abdominal supports would seem to be unjustified.

## Summary

This paper presents a study of 55 cases of nephroptosis seen at the New York Post-Graduate Hospital during the past decade. There is an appraisal of the operative procedure of nephropexy in the therapy of the low kidney and associated renal disease. Criteria are established for performing surgical intervention with a consideration of the technics employed. Follow-up studies are critically analyzed.

## CHEMOTHERAPY IN TUBERCULOSIS

Promin, diasone, promizole, and certain other related compounds appear to possess in varying degree the ability to restrain development of experimentally induced tuberculosis in guinea pigs. It is recognized that this offers many contracts with

able are as yet inadequate both quantitatively and qualitatively to permit, even tentatively, a positive evaluation of the curative effects of such drugs upon tuberculosis in human beings. Until controlled studies of adequate scope have been reported it is recommended that none of these drugs be used for treating tuberculous patients except under conditions which will add to our knowledge of their clinical action, and in the presence of adequate facilities

to protect patients effectively from their potentially serious toxic effects. Patients and physicians must be reminded of the Federal regulations which prohibit distribution of a drug in the experimental phase of development to other than research institutions to which the material is assigned by the manufacturer for either laboratory or clinical investigation.

Any use of chemotherapeutic agents in the treatment of tuberculous patients must, therefore, be regarded as a purely clinical investigation. It must be emphasized that such use is not without hazard and that the reviewed gives . . . than a critical patients.—Report of Committee on Therapy, American Trudeau Society, Am. Rev. Tuberc., Apr., 1944

# FACIAL PARALYSIS—PROSOPOPLEGIA\*

HAROLD R. MERWARTH, Comdr., (MC), USNR, Brooklyn

THIS presentation is a review of one individual's experience with paralysis of a single cranial nerve in 500 personally studied cases (see Table 1). In every instance the initial approach to these cases was due to the occurrence of a peripheral facial palsy, although in a few instances repeated examinations disclosed other associated neural findings. In order to demarcate the scope of this paper all cases have been eliminated in which, in addition to other findings, there later developed a peripheral facial paralysis.

The term "Bell's palsy" will be reserved for the occurrence of an acute "paralysis of undetermined origin," the connotations derived from its original description by Sir Charles Bell. Of all the causes of paralysis of the seventh cranial nerve, fallopian neuritis is by far the most common.

The seasonal incidence of facial paralysis in this series was as follows: January, 31; February, 28; March, 25; April, 24; May, 22; June, 23; July, 15; August, 9; September, 19; October, 13; November, 22; December, 15.

It is obvious from the above tabulation that there is no predilection for a particular season, although the three cold months of January, February, and March have a total of 84 cases as opposed to 43 observed in July, August, and September, the warm or mild months. It is the opinion of this writer that a particular season has no bearing on the occurrence of a facial paralysis.

Of the 304 cases of Bell's palsy examined in the acute phase of the "rheumatic" there were 153 females and 151 males (see Table 2). The sides involved were: in the females, 70 on the right and 82 on the left; in the males, 83 on the right and 63 on the left.

One hundred and ninety-five, or 63.3 per cent, of all patients are between 10 and 40 years of age, equally divided between the sexes.

## Onset

Although the patient is usually aware of the facial weakness because of a heavy, drawn feeling in the facial muscles, there are many instances in which a friend or relative calls the patient's attention to it because of the lack of expression and contortions in smiling.

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, May 5, 1943.

\* The material used in this paper does not include cases encountered in the Naval Service. The opinions expressed are the personal ones of the author.

Often the condition develops during the night, and in the morning the patient first becomes aware of the weakness by shaving, getting soap in the eye, gargling, brushing the teeth, or noticing an inability to spit. Occasionally the victim first becomes conscious of the condition on looking in the mirror. Inability to whistle made one man first aware of it; in another, an expert ear-wiggler, this simian quality was lost. One patient noticed an inability to make a Cupid's bow while applying lipstick. The inability to smile or laugh may first disturb the patient. A flickering of the eyelids or excessive winking may precede the actual weakness. The hostess of one patient excused herself from a guest because on observing the unusual winking of the eyelids she was led to believe that she was about to hear a juicy morsel of gossip.

Excessive salivation was observed in but one case, preceding the paralysis by three days.

See Table 3.

## Symptomatology

In Bell's palsy one encounters a variable symptomatology. The frequency with which the varied symptoms occur is as follows:

	Number	Percentage
Asymptomatic (paralysis only)	90	29.7
Loss of taste	144	47.3
Perversion of taste	110	36.1
Pain commonly retroauricular	123	40.4
Hyperacusis	24	7.8
Tinnitus	13	4.2
Vertigo	6	1.9

*Asymptomatic Cases.*—Only 90 patients (29.2 per cent) were completely free of associated symptoms. Five patients with a story of a previous attack later developed a symptomless second attack. Four were associated with pregnancy; and one had a bilateral involvement. The asymptomatic paralysis shows a tendency to rapid spontaneous recovery. All the patients with this type recovered except one.

This is quite in contrast to the patients with Bell's palsy who later develop a contracted state. Half of 30 patients with an old contracted palsy had no recollection of associated symptoms, while the other 15 recalled pain and taste disturbances at the onset. Also 9 of 10 acute cases, observed from the onset and later found to be contracted, had associated disturbances of pain and taste.

*Hyperacusis.*—Unusual sensitiveness to sounds ordinarily undisturbing was complained of by 24 patients (7.8 per cent). In three instances this

was more disagreeable and of greater concern to the patients than the palsy. In 6 patients it was the only symptom other than the palsy.

**Tinnitus**—The buzzing in the ear known as tinnitus was noted in 13 cases (4.2 per cent) and always was associated with retroaural pain, disturbances of taste or hyperacusis. The patients differentiated clearly between sensitiveness to sounds and in annoying buzzing in the ears.

**Vertigo**—Vertigo as a disturbing symptom is uncommon, having occurred in 6 cases. In most instances it antedates the paralysis and is of brief duration although in one instance it lasted for several days and was then followed by the facial paralysis. Four of the patients who suffered from vertigo had an associated disturbance of taste. Only one of this group complained of pain and then it was not the usual type found in the "rheumatic" kind of facial palsy.

There was no associated vascular hypertension, and in no case was there any suggestion of an aural infection. No impairment of hearing was found, and a disturbing tinnitus was noted but once.

**Case 1**—R. S., a woman of 52, had left facial paralysis. Her symptoms were suggestive of a possible labyrinthitis. Three weeks prior to the onset she had had a severe attack of vertigo, spinning around like a top and falling. Facial palsy came on while she was talking to her son. Distinct tinnitus occurred on the following day. The taste disturbance she described as "furry" and "metallic."

**Case 2**—The patient was a woman of 38 who complained of right facial paralysis. She noticed severe vertigo lasting all one day, and late in the afternoon she observed awkwardness in trying to drink a glass of water. Her taste was disturbed.

Testing showed a loss of taste. It was noticed that she breathed better through the left nostril.

**Case 3**—A man of 36 had left facial paralysis with severe vertigo at the onset. His taste was not disturbed subjectively and was intact on testing.

**Case 4**—The patient, a woman of 43, awakened one morning with paralysis. She felt very dizzy, but the dizziness disappeared during the day. Her taste was lost for seven days.

**Case 5**—A young man of 18 had severe symptoms of vertigo and also vomiting. Several days later a complete peripheral facial paralysis developed. The patient recovered.

**Case 6**—A man of 48 noticed right facial paralysis. At the onset he had had a dull pain and a feeling of swelling in the right side of his face. Subsequently he developed marked vertigo and a feeling of uncertainty in walking. He recovered.

**Pain**—Of 122 patients complaining of pain, most volunteered information but some (40 per cent) admitted pain only on questioning.

Of these, 103 patients had localized the pain behind the ear, usually over the mastoid process and in some cases deep between the angle of the jaw and the mastoid process. The retroaural pain usually develops concurrently with the onset of palsy. In 18 cases, the pain antedated the onset of paralysis as follows: in 4 by one day, in 5 by two days, in 2 by three days, in one by four days, in one by five days, and in 3 by seven days.

In two cases the pain was not complained of until after the development of the paralysis, in one patient by one day, and in 2 five days later. Ordinarily the pain gradually wears off after twenty-four hours.

In 19 others the pain was variously located in

TABLE 4.—RECURRENCE OF FACIAL PARALYSIS

Case			First Attack (Side)	Second Attack (Side)	Interval	Race	Remarks
1	F	58	Right	Left	1 month	Colored	Bell's palsy
2	F	64	Right	Left	25 years	White	Right side of face slightly contracted
3	F	81/4	Right	Left	6 years	White	First attack at 2 years—Bell's palsy
4	F	51	Left	Right	16 years	White	First attack—Bell's palsy. Second attack result of hypertension
5	F	60	Right	Left	15 years	White	Bell's palsy
6	F	60	Right	Left	4 years	White	Bell's palsy in second attack
7	M	75	Right	Bilateral	3 years	White	Second attack part of a toxic general peripheral neuritis
8	F	38	Right	Left	10 years	White	Bell's palsy
9	F	28	Right	Right	3 months	White	Recurred in course of 3 months
10	M	28	Left	Left	...	White	Attacks occurred during course of mastoid disease

the face, the angle of the jaw, down the neck, in the occiput, under the ear, and in one case it extended to the shoulder.

Other patients with dominant pain over the mastoid complained of additional pain in the neck, occiput, and face, and in one case in the ipsilateral nostril.

On two occasions patients were awakened at night by the severity of the pain, but in the great majority of the cases the pain is of a tolerable type. Occasionally it is shock-like or like a tooth ache, but most commonly one of a dull soreness. Its sharp localization over the mastoid process resulted on two occasions in operation with the resultant discovery of normal mastoid cells.

In seventy-six cases the pain was associated with a loss of taste sensibility. It was the only associated complaint in thirty-six cases.

**Disturbance of Taste.**—A disturbance of taste is the most common additional symptom, having been noted 144 times, or 47.5 per cent of the patients. As the only additional symptom, it occurred in 54 cases, or 17.7 per cent. It was discovered only on testing in 34 cases, or 11 per cent. In all 110 patients complained of taste disturbances.

In 11 cases there was consciousness of taste perversion and loss—in 3 the night before, in 3 two days before, in 2 the day before, in one three days, and in 2 seven days before the development of the paralysis.

The distortion of taste was variously described as copperish, bitter, sour, like acid, like aluminum, greasy, salty.

Although taste is not the most highly developed of the human senses, the loss of taste was recognized in 87 per cent of individuals affected. The fact that a perversion of taste occurred prior to the actual palsy is a point in favor of a progressive inflammatory agent, the taste perversion being a result of irritation of the chorda tympani nerve.

### Family History

In six of the cases there was a history of a

similar type of paralysis in another member of the family—all suffering from Bell's palsy.

The daughter of a woman of 42 with paralysis on the right side of the face also had it on the same side. Another woman of 18 with a right-sided paralysis had a sister who had been paralyzed at the same site several years before. One year previously the daughter of a woman patient 55 years old had developed facial paralysis on the same side as her mother. One patient had a brother who had had paralysis two years before and a sister three years before. The father of a 48-year-old man patient had had two attacks—the second at 81 years, just preceding the attack in the patient. The mother of still another patient of 43 had had a similar type of attack at 44 years.

The occurrence of a facial paralysis in several members of a family in so few cases (1 per cent) can hardly be advanced as an argument in favor of familial susceptibility. Its chance occurrence in a family serves rather as an indication of the frequency with which this nerve is implicated.

### Recurrence of Paralysis

In 1935 a series of 19 patients with a story of recurring attacks of facial paralysis was reported, of which 5 patients were observed in both attacks.

Since then 10 other patients have been observed in whom a second palsy developed.

The occurrence of a facial paralysis is apparently an unforgettable experience, as most patients recall, without prompting, the details of their initial attack. The frequency of a recurrence in a fallopian neuritis remains slightly over 7 per cent—23 of 304 cases with a history of Bell's palsy. In one the second attack was the result of a spontaneous aqueductal hemorrhage in vascular hypertension. In another there was a recurrence of bilateral facial paralysis, the result of a generalized toxic neuritis, all four extremities being involved also.

An unusual recurrence was observed in a pa-

tient with otitis media and mastoid disease. This patient, who suffered from a chronic discharging ear, developed in its course a facial palsy for which at that time a simple mastoidectomy was done. The face recovered in three weeks.

However, the aural discharge persisted, the facial palsy recurred, and eight weeks later a second operation was performed. Following the second operation the paralysis persisted without improvement for eight months.

See Table 4.

### Facial Paralysis Associated with Pregnancy

Twenty-one, or 40 per cent, of the cases were associated with pregnancy, and in one half of the cases it occurred in the first pregnancy. With the exception of three instances, all occurred in the latter part of pregnancy or shortly after delivery. There were 4 in the eighth month, and 6 in the ninth month before parturition, while 8 developed from one to nine days postpartum.

In all of the patients a typical story of the onset of Bell's palsy was elicited, there being no suggestion of a toxic factor. In one patient a vascular hypertension was found, but in this case a story of sharply localized retro-aural pain of an unusual length of fourteen days was obtained.

The concurrence of a Bell's palsy and pregnancy is of interest purely because of the apprehension it arouses in the patient, and at times in the attending physician. There is no logical explanation for this neural complication of a normal physiologic process. Its actual occurrence in this state is rather infrequent—only seven times in 27,243 deliveries in fifteen years on a single hospital maternity service.\* Of 304 cases of pure Bell's Palsy, 153 occurred in women (50%).

\* Methodist Episcopal Hospital, Brooklyn, New York.

### Etiology

Exposure or "refrigeration" has long been suspected as a causative agent.

In the experiences of this observer this theory of "refrigeration" would seem to be exploded by its infrequent occurrence, 13 patients only having provided a story indicating that they felt they had been exposed to a draft. Some of the reasons were unusual. They included "sleeping near an open window in August," "taking a bath the night before," "going without a hat," or "an auto ride in June."

Although the cold months should be more favorable, the cases supposedly caused by "exposure" do not necessarily develop in the cold period. Also if but 4 per cent have just a suspicion of "refrigeration," it cannot logically be regarded as a direct cause.

The cases are so few that they may be recorded briefly here.

*Case 1.*—A taxi driver first noticed a paralysis of the right side of his face when he was unable to expectorate through his open taxi window with his usual proficiency. It was September, and the left side of the face was the half exposed to a breeze while he was driving in his taxicab.

*Case 2.*—A woman, aged 31, felt that she was exposed to the cold on a damp, cold February day. She had retro-aural pain, tinnitus, and taste disturbance.

*Case 3.*—A man, aged 48, claimed that he was exposed to the cold on a cold day in December, although he had never been disturbed by equally cold weather.

*Case 4.*—A woman, aged 32, stated that she went out in the open air without a hat on a cold January day.

*Case 5.*—A girl, aged 12, had a swollen ankle four weeks before onset. Her mother attributed the paralysis to the fact that she had taken a bath at night just preceding the onset, in the month of June.

*Case 6.*—A woman, aged 21, attributed the onset of her paralysis to an automobile ride in June. The following day she observed pain in the left ear, and a day later a facial paralysis.

*Case 7.*—A boy, aged 18, felt that he had been exposed to the cold air on board ship.

*Case 8.*—A woman aged 18, sat in a draft at the movies. She noticed that her face felt swollen. Paralysis was present the following morning.

*Case 9.*—A girl, aged 11, had paralysis, which her mother felt had resulted from riding in a car in July, sitting in a draft in a theater, and going in swimming all in the same day.

*Case 10.*—A woman, aged 20, also claimed she sat in a draft in the theater.

*Case 11.*—A man, aged 26, in August slept all night with windows open.

*Case 12.*—A woman, aged 53, felt that she was exposed while on a boat trip in the month of April.

*Case 13.*—The single instance which could possibly be explained on the basis of exposure occurred in the following case:

A boy, aged 14, whose family was unable to procure a radio for him, used to sit night after night with his face glued against an intervening wall listening to a neighbor's radio. Although this was a nightly occurrence even in the cold months, it was in the warm month of July that a facial paralysis occurred on the side of his face which had been pressed against the wall.

The facial nerve is not more exposed to the outside world than any other nerve. At one point only is there a weakness in the protective armor and that involves one of its branches, the chorda tympani, which crosses the tympanic drum membrane. In a sense this nerve is just as exposed to potential infection as it is to "cold" as an agent.

In many cases there is a resemblance in the story to the cases of geniculate herpes. This is more so when the pain is widely diffused and not sharply localized over the mastoid process, and also when it occurs deep in the ear or anterior to the ear, spreading into the face. Even though herpetic vesicles cannot be found in these cases, a suspicion of a herpes virus (herpes zoster oticus) must be entertained.

The actual cause of the acute rheumatic type remains beclouded. The ease with which this nerve is involved in specific types of acute infection of the nervous system which are readily accepted as causes because the relationship seems clear-cut, indicates perhaps the intrinsic susceptibility of the facial nerve to other causes not so tangible or so easily proved. This relationship is particularly true of virus infection. In the series the onset followed the removal of an infected tooth, badly infected tonsils, and an attack of quinsy. Unfortunately, in the vast majority of cases there is no suspicion of illness, the patient being otherwise in excellent health.

In two instances only did the patients complain of headache.

It is the feeling of the writer that the cause of Bell's palsy is an infection—chiefly because of the associated pain and taste disturbances, both of which may precede the actual paralysis for days. A virus is the possible causative agent and may be related to that of herpes.

The frequency of paralysis is undoubtedly related to the unusually tortuous course of the seventh cranial nerve, rendering it readily susceptible to various types of injury and disease processes. It may be observed at birth and noted at an advanced age without favor to sex or race.

*Syphilis.*—All the patients with syphilis were examined because of the conspicuous features of the facial palsy, other findings being elicited in the course of a routine examination or revealed at a later period. There were 19 patients in whom the seventh cranial nerve was implicated in the presence of serologic or clinical proofs of syphilis. Of these, 10 cases of palsy were attributed directly to syphilis because of involvement of the adjacent cranial nerve, or positive changes in the cerebrospinal fluid with a paralysis of a pure motor type. The remaining 9 were those of a typical Bell's palsy occurring by chance in a patient who happened to have syphilis. Of the 10 cases caused by syphilis one remained throughout its course as an isolated paralysis without other cranial nerve involvement or neural changes elsewhere.

This patient, a man, aged 27, developed a left facial paralysis progressively over a few days. There was no pain, subjective or objective disturbances of taste, tinnitus, vertigo, or impairment of hearing. Clinical examination disclosed a 4 plus blood Wassermann with 350 lymphocytes and a 3 plus Wassermann in the cerebrospinal fluid. No evidence of internal hydrocephalus was found.

*Congenital.*—In rare instances the paralysis may be noted at birth independent of known causes such as syphilis or trauma caused by obstetric forceps. Four, or less than 1 per cent of the cases, were observed to be of this type.

The presumptive cause in the real congenital type is a nuclear agenesis, not inconsistent with embryonic developmental defects. One case examined sixteen years later showed diffuse muscular facial flutterings, observed in the contracted state of facial paralysis.

In 5 there were evidences of an active leptomeningitis, examinations of the cerebrospinal fluid revealing positive Wassermann reactions and a pleocytosis varying from 60 to 350 cells. Two of these cases showed papilledema. Seven cases provided indications of an involvement of the eighth nerve, such as tinnitus, vertigo, and

\* Present

impairment of hearing varying from partial to complete deafness, the three exceptions being the isolated palsy, described above. In another there was additional involvement of the homolateral abducens nerve, and the third developed in the course of tabes.

Of the 9 cases in which Bell's palsy occurred in association with serologic or physical signs of neural syphilis (9 cases with 4 plus blood Wassermann reaction) there was one instance of Erb's spastic paraplegia, and one in which there developed four years later a syphilitic spinal thrombosis.

Syphilis as a specific causative agent in these cases was eliminated by the story of retro-aural pain and taste disturbances. In a peripheral facial paralysis of acute onset, syphilis as a causative factor operates through compression of the nerve trunk in its intracranial course as it enters the internal auditory meatus in the company of the eighth nerve. Consequently there is usually an associated involvement of the eighth nerve, with resulting deafness of the nerve type. Although other neighboring signs may be present in the acute fulminating type of case simulating the cerebello pontine angle syndrome, a 'sub-acute' type exists in which the seventh and eighth nerves alone are implicated.

It is just as common for the nerve to be involved in an acute inflammatory fashion coincidental with syphilis as by syphilis alone.

See Table 6

**Mastoid**—Facial paralysis in relation to aural disease disturbs both surgeons and patients. Fifty-three cases in the series were related to a chronic discharging ear. Preoperative onset of the paralysis was observed in 11 patients. Three other patients did not submit to an operation. In one instance there was an interval of thirty days between the onset of the paralysis and the

operation. A contractural muscle state developed in 2 of these patients. One of these had refused surgery. In the other the contracture developed where the mastoidectomy was performed. Two patients with severe facial pain subsequently died of an infection of the petrous tip.

In 39 patients the paralysis was observed after the operation. In 30 patients the palsy was noted within the first twenty-four hours. The time of onset of the paralysis in relation to the operation was as follows:

Number of Cases	Time of Onset of Paralysis (In Relation to Operation)
7	Immediately
15	12 hours after
8	24 hours after
1	2 days after
3	3 days after
1	4 days after
1	5 days after
2	7 days after
1	3 days after

Six patients in whom there occurred a post-operative facial paralysis observed within the first twelve hours, later developed a contractural state. The 16 patients in whom the paralysis definitely occurred before the operation or after an observed period of delayed onset following the operation, recovered completely. The factor causing the palsy was definitely not related to the surgeon's chisel or rongeur.

**Trauma**—There were 26 cases of palsy of the facial nerve as the result of trauma through accident—as follows: 6 from falls (one fell as a baby, 2 fell down subway stairs), 6 from automobile accidents, one from riding a sled which hit a tree, 4 from head injury (precise cause not determined), 2 from forceps injury, one from a tear from an elephant's tusk, 2 from bullet wounds, 2 from cuts by glass, one from getting

his head caught in a vise; one from having a nerve torn by a spike.

Injury to the facial nerve acquired as the result of a basal skull fracture is usually accompanied by bleeding from the homolateral ear. Usually this type of paralysis is the result of a head injury of a severe degree and is associated with periods of unconsciousness of varying duration. Of the 17 patients so injured the paralysis cleared up except in 4, who developed a contractural state.

In 4 other cases there was a definite delay in the onset of the paralysis following severe injury to the base of the skull. Two developed it three days after the accident, one four days later, and in a fourth it was not observed until ten days after the accident.

The mechanism of slow onset is obscure. It may possibly be (1) compression from hemorrhage or (2) injury to the blood supply to the nerve itself. There was no positive evidence of the development of a mastoiditis in these cases.

Damage to the nerve through faulty application of the forceps is rather unusual, but 2 cases having been noted, both of which recovered. Its infrequency is testimony to the modern training of the obstetrician.

One striking complete peripheral nerve laceration occurred in a man aged 71, who while trying to repair his barn was impaled by a large spike which had been driven through 2-by-4-inch scantling. The spike penetrated the right cheek, cutting the right facial nerve just prior to its entrance into the parotid gland.

Of interest both in "mastoid" and trauma are the cases that developed later, after the original ictus, there being 9 following mastoidectomy and 4 following trauma. Because of the nature of the associated trauma, operative in one and accidental in another, the correct evaluation of pain, taste disturbances, and hyperacusis could not be determined. In both cases the paralysis seemed to be the logical result of a disturbance

within the fallopian canal, possibly hemorrhage or edema, although consideration must be given to an independent neuritic factor, particularly in the cases of belated postoperative onset.

*Hypertension.*—There were 28 cases of facial paralysis in which vascular hypertension was found, 18 of which were believed to be the result of hemorrhage into the facial aqueduct. Sixteen were previously reported (see Table 7).

The 2 additional cases developed as follows:

M. C., a woman aged 51, a known hypertensive noticed while sitting in a church pew a sudden quivering of the entire right side of the face and immediate inability to move the muscles of her face. Sixteen years previously she had had an attack of Bell's palsy which affected the opposite side of her face; hence she was familiar with the symptoms. When she was examined two days after the onset there was a complete right peripheral facial palsy. The blood pressure was 210 over 120 mm. Hg. Pain was absent. There was no disturbance of taste.

C. Z. (Case 18), a man aged 50, developed an attack of dizziness of sudden onset and marked degree, with buzzing and impairment of hearing of the middle-ear type in the left ear, associated with an immediate facial paralysis. He had been treated for hypertensive vascular disease and had been suffering from attacks of headache and vertigo. The blood pressure was 220 over 110 mm. Hg. There was no local pain.

It is the opinion of the writer that the cause of sudden facial paralysis from hypertensive vascular disease is bleeding from the petrosal artery which enters the upper limits of the facial canal at its constricted portion. Interruption of the blood supply would disrupt the circulation to the facial nerve trunk supplied by vasa nervorum arising from the petrosal artery. This theory is supported by the location of hemorrhage in cases reported by Moxon, and that of Monia-Vinard and Pueil.

See Table 8.

TABLE 8.—CONTRASTING FEATURES

	Bell's Palsy	Hypertension
Age, percentage	Young adults, 68% before 40	Higher decades (after 40)
Perversion of taste	Present in 110 of 304 cases	Absent
Pain	Present in 123 of 304 cases. Retro-aural common antedating paralysis	Absent
Onset	Frequently gradual	Always precipitate
Recurrence	23 of 304 cases	No recurrence
Associated physical signs	None	Vascular hypertension, arteriosclerosis
Significant history	Absent	Previous headache, vertigo, known high blood pressure, or bleeding elsewhere, brain retinal

## Herpes

*Case 1.*—A 43-year-old woman with herpes of the ear developed left-sided facial paralysis in June, 1933; the patient recovered.

*Case 2.*—A 9-year-old girl developed right-sided facial paralysis with severe pain in February, 1928. She was suffering from herpes of the external auditory meatus. Later facial nerve anastomosis was performed.

*Case 3.*—In May, 1938, a 56-year-old woman with herpes of the ear and left side of the face with impaired sensation in the left fifth cranial nerve developed left-sided facial paralysis with severe pain. The patient recovered; she died of cancer years later.

*Case 4.*—A 49-year-old woman developed complete left-sided facial paralysis in June, 1928. She had herpes of the aural canal with pain in the ear. She later recovered.

*Case 5.*—A 52-year-old woman with herpes of the left ear and aural canal and concomitant involvement of the left fifth facial nerve developed left-sided facial paralysis, from which she recovered.

*Case 6.*—A 56-year-old man with facial herpes developed right-sided facial paralysis and vertigo.

## Contractural Facial Paralysis

Fifty-seven instances of contractural facial paralysis were observed, of which 40 were of the acute inflammatory type. The remaining 17 resulted from the following causes: mastoid disease, 8; trauma, 3; meningitis, 1; syphilis, 1; congenital, 1; unknown, 3.

Of the 40 cases of acute Bell's palsy, 30 presented themselves for the initial examination with a facial palsy in varying degrees of a contractural state. Ten patients first examined during the acute phase when examined after periods of months to three years were found to possess a contractural facial paralysis.

## Myoclonic Facial Paralysis

In many respects myoclonic facial paralysis

TABLE 9.—MYOCLONIC FACIAL PARALYSIS

Case	Sex	Age	Side	Remarks
1	M	40	Right	..
2	M	42	Left	..
3	F	63	Left	Patient was a nurse
4	M	18	Left	..
5	F	46	Left	..
6	F	37	Right	..
7	F	62	Right	Trauma
8	F	65	Left	Arteriosclerotic

15	F	40	Right	..
16	M	48	Left	..
17	M	23	Right	Patient also had otitic hydrocephalus
18	M	44	Right	Patient was colored. Brief periods of freedom. Lasted 5 years. Eye affected first.
19	M	42	Left	..

is a mystery more disturbing than a contracted facial paralysis because of the coarse irritative muscular movements, the spasmodic twitchings being mainly centered about the eyes and mouth.

A point of interest observed in 2 cases, and described in a third, is the tendency to spontaneous remission.

Although this is not strictly a facial palsy, in long-continued cases there is a moderate paresis of the facial musculature. On casual inspection the badly contracted facial paralysis, with the diffuse fibrillary movement, and the myoclonic facial spasm with its muscular fascicular twitchings, bear a close resemblance. In the contracted facial palsy there are no periods of relaxation such as are characteristic of facial myoclonic spasm.

See Table 9.

## Bilateral Facial Paralysis

Most commonly, both halves of the face are implicated as a local manifestation of a generalized neuritic involvement. There were 8 patients with both halves of the face involved at the same time. However, 3 of these cases were of the Bell's variety, with all the characteristic symptoms.

Another developed a polyneuritis with bi-facial implication, two years following recovery from an attack of rheumatic facial paralysis. In still another the facial involvement was the sole manifestation of an inflammatory process involving the central nervous system, the cerebrospinal fluid showing a pleocytosis.

## Summary

1. Statistical analysis of 500 personally studied cases is the purpose of this paper.
2. Three hundred and four cases belonged to the group of acute "rheumatic type," or Bell's palsy.
3. In addition to the acute type, trauma (23 cases) and mastoid disease (53) constitute the major causes.
4. Of the symptoms associated with Bell's palsy, pain occurred in 122 cases, or 40 per cent,

and taste disturbance was noted in 144 cases, or 45.5 per cent.

5. Refrigeration, or exposure to cold, as a cause of the acute type occurred but thirteen times in 304 cases. There were 21 patients whose paralysis was associated with pregnancy, usually near term.

6. Hypertensive arteriosclerotic vascular disease was a causative factor in 18 cases.

7. The facial nerve has a tendency to spontaneous recovery, best noted in patients with a pure motor paralysis.

## JOURNAL OF NEUROSURGERY

The publishing of a new journal devoted to neurosurgery adds to the firm foundation of this branch of medicine. Neurologic surgery developed largely in this country as the result of the stimulus given to it by Harvey Cushing, who began publishing papers on the subject as early as 1900 and continued up to the time of his death in 1939. A society of neurosurgeons named in his honor has now established a journal with an editorial and advisory board that reflects the widespread interest in this subject. The chairman of the board is Dr. Gilbert Horrax, of Boston, long associated with Dr. Cushing at the Peter Bent Brigham Hospital. Other members are from Chile, Canada, England, and Sweden. It is presumed that after the war representation from other parts of the world in which neurosurgery flourishes will appear on the editorial committees. The managing editor, Dr. Louise Eisenhardt, of New Haven, Connecticut, was also closely associated with Dr. Cushing for many years, and she collaborated with him in his final great volume reporting his surgical experience with meningiomas. Dr. Eisenhardt is head of the Brain Tumor Registry at

the New Haven Hospital, an undertaking begun by Dr. Cushing, where many specimens from other clinics are examined yearly and compared with those already on file.

In the first number of the *Journal of Neurosurgery*, Dr. Horrax describes some of Harvey Cushing's contributions to the subject, reviewing the development of the technic of surgical exploration of the cranial contents by this master. Another paper deals with fibrin foams as hemostatic agents and with fibrin films in the repair of dural defects and in the prevention of meningocerebral adhesions; the authors are Dr. Franc D. Ingraham and Dr. Orville T. Bailey, of the Harvard Medical School and the Children's Hospital. These and other contributions make the first number of this journal an important addition to medical literature. The illustrations are excellent, many of them being in color. This journal, therefore, is indeed a welcome addition to medical literature, and with the fine standards set up by the initial number the editor and her editorial advisers are open to sincere congratulations.—*New England J. M., May 4, 1944*

## TOOTHsome GUAVA HELPS TO KEEP UNITED STATES FIGHTING MEN FIT

The common or garden guava, a perennial favorite among dessert-loving Latin Americans, is now playing an important part in helping to keep United States servicemen fit and happy. Because guava has a Vitamin C content from ten to twenty times that of other fruits used in making jams and jellies, the War Department is adding it to apples, oranges, apricots, peaches, grapes, and other fruits used in making spreads.

Ten per cent of guava added to other fruits in the preparation of jams and jellies more than doubles the Vitamin C content of the mixture. In other words, one pound of guava contains as much of the scurvy-preventing vitamin as nine pounds of the other fruits named.

As the Vitamin C content of guava varies widely in accordance with the variety of the fruit and its ripeness, scientific cultivation might produce high-yielding strains with an even higher vitamin content than the wild fruit which is now largely used in Latin American countries.

Guavas, sometimes known as guayaba, flourish throughout tropical America and have been introduced successfully in India and South Africa. A factory was recently built in South Africa to dehydrate the fruit and convert it into a powder used in supplementing the diet of British soldiers.

On this continent, the fruit has been a favorite for centuries with the natives of other American republics. Spread on bread or crackers, or served as a dessert with cheese, it is an inevitable part of a well-planned meal anywhere in Spanish America.

The manufacture of guava jellies and jams is an important industry in Cuba, Puerto Rico, Brazil, and other American countries. Brazil alone has more than four hundred small factories producing guava jellies for the domestic market, and a United States company has established a plant in Mexico to quick-freeze guava pulp for use in the United States in the manufacture of ice cream and ices.—*Release from the Office of the Coordinator of Inter-American Affairs*

# STABILITY OF THE FASTING BLOOD SUGAR IN DIABETES MELLITUS

HERMAN O. MOSENTHAL, M.D., and FRANCES U. LAUBER, B.A., New York City

**A** DETERMINATION of the blood sugar in the fasting state is insisted on by most laboratories, hospitals, and physicians for the management of diabetes mellitus. The reason for this is twofold: first, that the blood sugar level at the time of food abstinence represents the true degree of control of the carbohydrate metabolism that has been accomplished by diet, or by diet and insulin; and, second, that in the fasting state the blood sugar is as immutably fixed as a lighthouse. Most internists feel secure in the effectiveness of the prescribed therapy when the fasting blood sugar is normal, and most surgeons are willing to operate under those circumstances.

A series of hourly determinations of fasting blood sugars was made on 70 diabetics over a period of three hours, with the idea of testing out

fasting blood sugar in the course of three hours might drop or rise considerably or remain fixed.

The possibility that protamine insulin acts for more than twenty-four hours and might depress the fasting blood sugar has to be considered.

However, there were a considerable number of patients receiving protamine insulin whose blood sugar did not fall but rose, and there were also many instances in cases under treatment with globin or regular insulin (the effect of which is not supposed to last for more than twenty-four hours) of a rise in blood sugar. This verifies the conclusion made some time ago that in all diabetes the protamine insulin does not act for as long as twenty-four hours. It is evident that either an increase or a diminution in the fasting blood sugar may occur in the course

TABLE 1—SPONTANEOUS CHANGES IN BLOOD SUGAR WITHIN THREE HOURS IN RESTING FASTING DIABETICS WITHOUT INSULIN ON THE MORNING OF OBSERVATION\*

\* Seventy cases studied, ages 10 to 65. Only 21 cases are classified "with the maximal drop 7 with the maximal rise and 7 with a minimal change. The utility of regarding the fasting blood sugar as a fixed value is evident.

† Globin insulin (with 210) is designated as G, and protamine zinc insulin as P. Since by many observers, including ourselves, crystalline and unmodified (regular) insulins are believed to have an almost identical effect upon the blood sugar, these two forms of insulin are allied to by one letter—R.

the validity of the current conceptions in regard to fasting blood sugars. Capillary blood sugars were determined according to the micro method of Lauber and Mattice.<sup>1</sup> Table 1 shows that the

of three hours regardless of the type of insulin used.

The number of cases showing an insignificant change in the blood sugar—that is, less than 11 mg. per 100 cc—was 25, or 36 per cent, of the total number (Table 2). A slight drop—that is, 11 to 20 mg. per 100 cc—in the blood sugar was noted in 12, or 17 per cent of the cases, and a moderate drop, 21 to 40 mg. per 100 cc, was

From the Research Division of the New York Diabetes Association Inc.

Contributions by Mr. Felix Morgenstern to the Research Division of the New York Diabetes Association Inc. supported this project.

TABLE 2—SUMMARY OF THREE-HOUR CHANGES IN THE FASTING BLOOD SUGAR OF 70 PATIENTS WITH DIABETES MELLITUS

Variations in Blood Sugar Mg. per 100 Cc.	Total Number	Number of Cases Drop in Blood Sugar	Rise in Blood Sugar
0 to 10 (insignificant)	25 (36%)	12 (17%)	1 (1%)
11 to 20 (slight)	13 (18%)	15 (21%)	5 (7%)
21 to 40 (moderate)	20 (29%)	7 (10%)	5 (7%)
41+ (marked)	12 (17%)	—	—
Total	70 (100%)	34 (48%)	11 (15%)

noted in 15, or 21 per cent, of the cases, and a marked drop—that is, more than 40 mg. per 100 cc.—existed in 17 cases, or 10 per cent of the total number. A slight rise in blood sugar (less than 11 mg. per 100 cc.) occurred within the three-hour fasting period in one case, and a moderate increase (21 to 40 mg. per 100 cc.) in 5, or 7 per cent, and the same numbers showed a marked elevation (41 mg. per 100 cc., or more).

Those showing a drop in blood sugar exceeded the number of cases exhibiting a rise, there being 34 patients, or 48 per cent, whose blood sugar became lower during the fasting period, while 11, or 15 per cent, showed a rise. It may be

concluded that in about two-thirds of diabetics there is a significant change in the blood sugar during a three-hour fasting period, a rise being about three times as frequent as a drop in the blood sugar.

### Conclusion

The fasting blood sugar over a period of three hours in 70 fasting diabetics showed a significant change in the blood sugar values in 63 per cent of the cases. In 48 per cent there was a drop in the blood sugar, and in 15 per cent a rise. Consequently, the interpretation of the fasting blood sugar as a fixed quantity and an absolute guide to the status of the diabetes is not valid. Since the determination of fasting blood sugars often disrupts the day's routine as far as the administration of insulin and the time of breakfast are concerned, and may entail a good deal of nervous strain for the patient, it would seem preferable, at least in those diabetics who are not confined to a hospital, to obtain the blood some time after breakfast and make the proper allowances in evaluating the blood sugar.

## BOARD OF OBSTETRICS AND GYNECOLOGY MEETS IN PITTSBURGH

The annual meeting of the American Board of Obstetrics and Gynecology was held in Pittsburgh, Pennsylvania, from June 7 to June 13, 1944, at which time ninety-three candidates were certified.

A number of changes in Board regulations and requirements were put into effect which were designed to aid civilian candidates as well as those in the service. Among these is the waiver, temporarily, of our A.M.A. requirement for men in the Army or Navy, especially for those who proceeded directly, or almost so, from hospital services into Army or Navy service, upon a statement of intention to join promptly upon return to civilian practice. At this meeting the Board also accepted a period of nine months as an academic year in satisfying our requirement for certain years of training.

This is only for the duration, and even men who are not eligible for military service but who are nevertheless in hospitals where the accelerated program is in effect have been allowed to submit to us this short-time period of training in lieu of our previous requirements.

Beginning with the next written examination, which is scheduled to be held the first Saturday afternoon in February, 1945, this Board will limit the written examination to a maximum period of three hours, and in submitting case records at this time, all candidates' case abstracts whose ob-

stetric reports do not include measurements either by calipers or, as indicated, by acceptable x-ray pelvimetry, will be considered incomplete.

Prospective applicants or candidates in military service are urged to obtain from the Office of the Secretary a copy of the *Record of Professional Assignments for Prospective Applicants for Certification by Specialty Boards*, which will be supplied upon request. This record was compiled by the Advisory Board for Medical Specialties and is approved by the Offices of the Surgeons General, having been recommended to the Services in a circular letter, No. 76, from the War Department Army Service Forces, and referred to as the *Medical Officer's Service Record*. These will enable prospective applicants and candidates to keep an accurate record of work done while in military service and should be submitted with the candidate's application, so that the Credentials Committee may have this information available in reviewing the application.

Applications and *Bulletins* of detailed information regarding the Board requirements will be sent upon request to the Secretary's Office, 1015 Highland Building, Pittsburgh 6, Pennsylvania. Applications must be in the Office of the Secretary by November 15, 1944, ninety days in advance of the examination date. The time and place of the Spring, 1945 (Part II), examination will be announced later.

# CUTANEOUS MANIFESTATIONS OF TUBERCULOSIS

ANTHONY C. CIPOLLARO, M D, New York City

THE manifestations of cutaneous tuberculosis vary widely. The clinical varieties are many, and their classifications are unsatisfactory. There are three general groupings: (1) according to histologic changes, (2) according to immunologic reactions, and (3) according to clinical types. The most widely accepted classification is that of Gans,<sup>1</sup> who divides tuberculodermis into two large groups. In one group are forms of cutaneous tuberculosis which are localized and spread from an initial infected spot, and in the other are those which are widespread and are disseminated by hematogenous routes.

## A Localized tuberculosis

- 1 Primary tuberculous complex
- 2 Tuberculosis verrucosa cutis
- 3 Tuberculosis cutis orificialis
- 4 Scrofuloderma
- 5 Lupus vulgaris

## B Hematogenous types

- 1 Acute milium tuberculosis
- 2 Papulonecrotic tuberculid

All the varieties of tuberculodermas are caused by the tubercle bacillus. The differences in clinical and histologic characteristics can be accounted for by the differences in immunologic reactions, attenuation of organisms, environmental factors, and the like. The bacillus of Koch is frequently found in lesions of acute milium tuberculosis and less frequently in lupus vulgaris, tuberculosis cutis orificialis, tuberculosis verrucosa cutis, and rarely is found in papulonecrotic tuberculid, rosacea-like tuberculid of Lewandowsky, lichen scrofulosus, erythema induratum, and hardly ever in the sarcoids. In some the histology is frankly tuberculous, and in others it suggests tuberculous reactions or is tuberculoid. The tuberculin reactions vary all the way from strongly positive to negative. In fact, in the sarcoid group the tuberculin reactions are less sensitive than in a normal group.

Cutaneous tuberculosis is not rare, but it is unusual in the United States. It is much more common in Europe. Cases observed in the United States are usually in the foreign-born or immediate descendants of immigrants. Tuberculodermas occur more frequently in children and young adults than in older individuals. However, because of the slow progress of the disease, the destructive types, such as lupus vulgaris and ulcers, are seen in older individuals. In some instances the progress is arrested as a result of the development of natural immunity. Tuberculosis of the skin is rarely seen in sanatoriums for tuberculosis.

Formerly many conditions were considered to belong to the group of tuberculodermas. In a few instances the causative organism of these conditions is the tubercle bacillus, but in most cases it is something else. The diseases which were formerly considered to be caused by the bacillus of Koch are lupus erythematosus, granuloma annulare, erythema nodosum, lichen nitidus, and acne cachecticorum. The literature is extremely confusing when it comes to terminology. Many different names have been used to describe the same disease. As, for example, papulonecrotic tuberculid would be called folliculitis, acnitis, hidradenitis destruens suppurativa (Politzer), and many others.<sup>2</sup> These descriptive terms have made it very difficult to satisfactorily classify all forms of cutaneous tuberculosis. More recently Jadassohn has suggested the use of the term "tuberculosis" to be followed by a qualitative adjective for designating the various forms of cutaneous tuberculosis. This has added to the confusion which already exists.

## Localized Tuberculodermas

**Primary Tuberculous Complex**—The primary complex of tuberculosis is a rare form of cutaneous tuberculosis.<sup>3</sup> It is seen in children, and several instances of this condition have been reported in adults who never before were infected by the bacillus of Koch, either in the skin or in any other organ. Tubercle bacilli invade the host from some exogenous source. At the site of inoculation an ulcer (tuberculous chancre) appears. There is lymphangitis and lymphadenitis as well as some elevation in temperature. Tuberculin reaction following inoculation is positive, whereas prior to inoculation it was negative.

Most of the earlier cases were encountered after ritual circumcision of infants, where the officiat-

ing rabbi, who harbored tubercle bacilli, sucked the wound after cutting the prepuce.

The primary complex of tuberculosis of the skin is equivalent to that of the Ghon tubercle in the lungs and other internal organs. This disease may occur on any part of the body. The lesion heals within several months, leaving a scar at the affected site.

Treatment with x-rays may speed involution of such lesions. Localized and generalized ultraviolet irradiation is beneficial. Surgical excision and tuberculin therapy may be used in selected cases.

*Tuberculosis Verrucosa Cutis.*—This disease occurs both in those who have active tuberculosis and in those who have been exposed to tuberculosis but are without any clinical evidence of the disease. There are three main sources of contamination:

1. From tuberculous cadavers—pathologists, anatomists, and medical students fall victim to this source of contamination.
2. From infected animals—butchers, veterinarians, and meat inspectors fall victim to this source of contamination.
3. From tuberculous sputum—patients with active pulmonary tuberculosis fall victim to this source of contamination.

The usual site of infection is the dorsum of the hands and fingers. The lesions begin as small wart-like papules. They increase in number and coalesce to form plaques. They may be round or oval, and are dark red or purplish in color. There may be some exudation and crusting. Lesions may be single or multiple and occasionally are frambesiform and vegetative. The lesions spread by peripheral extension and sometimes undergo spontaneous healing. At the periphery of the lesion is an area of infiltration which serves to differentiate a tuberculous wart from a common wart. Following inoculation, especially in a healed tuberculous subject, there may be lymphangitis, lymphadenitis, and slight elevation of temperature.

*Verruca necrogenica*, described by Laennec, is a variant of tuberculosis verrucosa cutis.

Conservative treatment is indicated for these lesions. Treatment with x-ray yields excellent results. Ultraviolet irradiation may be used. In uncomplicated cases the lesions may be excised, either by scalpel or by electrosurgical current. Bed rest is indicated in the presence of constitutional symptoms.

*Tuberculosis Cutis Orificialis.*—This variety of cutaneous tuberculosis represents a direct extension and is secondary to active tuberculosis of the internal organs. For example, orificial lesions of the penis are probably secondary to tubercu-

losis of the kidney. Lesions about the nose, mouth, and tongue are probably secondary to tuberculosis of the lungs. When lesions of tuberculosis cutis orificialis occur it generally denotes a terminal stage of visceral tuberculosis. It indicates a complete breaking down of resistance to the tubercle bacillus. The patients are always in poor general health, and the earliest lesion is a yellowish miliary tubercle or nodule which soon coalesces with other nodules and quickly breaks down, forming round or oval sluggish and granulating ulcers. The lesions are very superficial and soft. The edges are irregular and the floor is uneven. When ulcers occur on the tongue they are usually longitudinal and they are accompanied by pain. The tuberculin reaction is usually negative.

Lesions of tuberculosis cutis orificialis respond extremely well to x-rays. Thus some temporary comfort to the patient ensues, but the final outcome of the disease is unaffected. Methods of treatment which add to the discomfort of the patient should not be instituted.

*Scrofuloderma.*—This term is restricted to those cases in which the skin is involved secondarily by direct extension from tuberculous nodules, lymph glands, or bones. The cervical lymph nodes in children are most commonly affected.<sup>3</sup> The disease usually begins as subcutaneous nodules which become progressively larger. They are painless and the overlying skin is bluish-red in color. Gradually the skin becomes thin, atrophic, and, as a result of liquefaction necrosis, ulceration occurs at one or more points. The ulcerated lesions are round or oval and really represent the mouths of sinuses which extend deep into the lymph glands. There is a constant discharge of seropurulent-like material. The lesions heal very slowly, with scar formations which are often contracted and disfiguring.

The treatment of choice for many varieties of scrofuloderma is roentgen therapy. Total excision of the infected nodes is preferable to incising and draining a fluctuant node. Ultraviolet radiation is beneficial, especially for the large ulcerative lesions. As in all forms of cutaneous tuberculosis, particular attention should be paid to general hygienic and systemic measures, which should include a high vitamin and salt-poor diet.

*Lupus Vulgaris.*—Lupus vulgaris is an ulcerative, gnawing, and devouring disease which starts early in life. The untreated cases become progressively worse. The face and upper extremities are affected in approximately 85 per cent of the cases. Lesions may appear, however, on any part of the body. The very first lesion of lupus vulgaris is a small subcutaneous nodule which on diascopic pressure presents the golden-brown color resembling apple jelly. The term

"apple-jelly nodule" is commonly used to designate this change. As the disease progresses new nodules develop and arrange themselves in plaque formation. Ulceration ensues and finally scars form. There is peripheral extension and central healing in well-marked longstanding cases. The contraction of the scars leads to deformities. The lesions are usually sharply demarcated and the color is dark red or purplish. There are no subjective symptoms. Lupus vulgaris may assume extremely varied appearances. Many different adjectives have been used to describe these various forms. The three most common types encountered are lupus planus, lupus tumidus, and lupus hypertrophicus. The many other adjectives used to describe the different varieties of lupus vulgaris will not be given, as they only serve to confuse the picture.

There is no specific remedy for the treatment of lupus vulgaris. Systemic treatment and hygienic measures such as are used in treating pulmonary tuberculosis are most essential. Some state that good results have been obtained with a diet high in vitamin content and low in sodium chloride. Tuberculin therapy has also been found to be valuable. Generalized and localized ultraviolet irradiation, particularly with the Finsen light, over a prolonged period of time, has been helpful in some cases. Very early, small, new lesions are probably best treated by excision or by electro-surgical destruction. X-rays and radium are of value in selected localized cases. Injections with gold sodium thiosulphate have been found to be of little or no value in the treatment of lupus vulgaris.

### Hematogenous Types of Cutaneous Tuberculosis

The forms of tuberculodermas belonging to this group have an extensive and symmetric distribution, and spread by way of the hematogenous route. The method of spread really represents a tuberculous septicaemia. However, all of the entities, with the exception of acute miliary tuberculosis, are not serious from the standpoint of danger to life. All forms of hematogenous tuberculodermas are caused by the tubercle bacillus, and the only justification for their being grouped under this heading is because of the method by which the disease extends.

*Acute Miliary Tuberculosis.*—This disease is rare and occurs for the most part in children. It is a cutaneous manifestation of generalized visceral tuberculosis which occurs in those with pulmonary tuberculosis and little or no immunity to the bacillus of Koch. The disease is fatal and death is most often due to tuberculous meningitis. The lesions are generalized and may be either purpuric papules, vesicles, or pustules. Even

small ulcers covered with crusts sometimes form.

When systemic tuberculosis becomes so extensive as to produce lesions on the skin and in the meninges, no method of treatment is effectual.

*Papulonecrotic Tuberculid.*—This disease is uncommon and occurs in young adults. The upper and lower extremities and the face are the usual sites of involvement. The trunk may also be affected. The lesions are probably produced by hematogenous showers of attenuated tubercle bacilli. They begin as tiny dull-red elevations which are sharply circumscribed, isolated, firm, and painless. They are symmetrically distributed. Soon after the appearance of the papules central necrosis takes place. Ulcerations form which heal within a few weeks, leaving atrophic scars with hyperpigmented borders. As a rule lesions in different stages of involution and evolution are seen at the affected sites. Occasionally they occur concomitantly with erythema induratum of Bazin.

In treating this condition it is important to pay particular attention to general hygiene and to nutrition. Generalized and localized heliotherapy is of value, and treatment with antiseptic topical remedies may hasten involution.

*Lupus Miliaris Disseminatus Faciei.*—This variety of hematogenous tuberculoderma occurs most commonly on the face of adults, especially in young Negroes.<sup>6</sup> The lesions consist of small papules which do not ulcerate and which on diascopic pressure show typical apple-jelly nodules. They are situated along the edges of the eyelids, the mucocutaneous junction of the lips, and about the nares. They occur in crops and persist for months or years. When they undergo spontaneous involution they leave scars which are barely perceptible. The histology so closely resembles lupus vulgaris that the opinion has been expressed that these lesions may represent an unusual form of lupus vulgaris.

In treating lupus miliaris disseminatus faciei one should be guided by the same principles as those utilized in the treatment of lupus vulgaris. Those destructive methods which leave scars should not be utilized, since most cases heal spontaneously. Treatment with tuberculin and ultraviolet radiation are efficacious.

*Rosacea-Like Tuberculid of Lewandowsky.*—This condition is so named because of its marked resemblance to ordinary rosacea.<sup>7</sup> It occurs usually in adults. The lesions consist of discrete or conglomerated papules which are slightly elevated and whose color varies from bright red to brownish red. They are situated on the forehead, cheeks, and chin. The nose and the glabella are generally free of lesions. On diascopic pressure the characteristic apple jelly nodule is elicited.

TABLE 1.—LOCALIZED TUBERCULOSIS

Name of Disease	Clinical Signs	Histologic Characteristics	Tuberculin Reaction
Lupus vulgaris	Apple-jelly nodules. Dark red coalescing nodules forming plaques on face, nose, ears, etc.	Tubercles only in the subcutis at times. Tubercles plus inflammatory reaction in any part of the cutis, more specifically in the subcutis.	Hypersensitive
Tuberculosis verrucosa cutis	Solitary verrucous patches on dorsum of hands occurring in tuberculous subjects, prosectors, etc.	Tubercles with inflammatory process and granulation tissue with marked epithelial changes.	Hypersensitive
Tuberculosis cutis orificialis	Ulcerations of mucous membranes or skin of orifices	Tubercles with inflammatory process and granulation tissue with marked epithelial changes	Anergic
Scrofuloderma	Ulcerations of the skin overlying lymph nodes	Tubercles with inflammatory process and granulation tissue in the subcutis with ulceration and sinus formation.	Hypersensitive
Primary tuberculous complex	Ulceration at site of inoculation, with lymphangitis and lymphadenitis and fever	Characteristic tuberculous histology with finding of tubercle bacilli.	Hypersensitive

Occasionally both rosacea and rosacea-like tuberculid of Lewandowsky occur in the same individual. Subjective symptoms are absent and usually there is no evidence of visceral tuberculosis. The histologic picture is that of tuberculosis, and the tuberculin reaction is usually positive.<sup>8</sup>

These lesions respond to a variety of measures. Intravenous or intramuscular injections of gold salts and tuberculin therapy are perhaps the two best methods of treatment. Some cases do very well with exfoliating topical remedies combined with moderate doses of ultraviolet radiation. This condition is particularly resistant to roentgen therapy.

*Lichen Scrofulosus*.—Lesions of this disease occur on the trunk and less frequently on the extremities. They consist of small, pinhead-size, flattened papules which are slightly elevated. The color varies from dusky red to that of normal skin. The papules are so small that they often escape detection. Occasionally there is a tiny scale over the papules. The lesions are usually located about the hair follicles. The condition may appear suddenly and may persist for many months. When the lesions disappear no scars remain. Tuberculous children and young adults are most frequently affected. The tuberculin reaction is positive and the histologic picture is that of true tuberculosis.

In the absence of active visceral tuberculosis, treatment with ultraviolet rays and tuberculin injections is satisfactory.

*Erythema Induratum of Bazin*.—This disease is chronic and tends to recur. It occurs as a rule on the backs of legs of girls and young women whose occupation requires them to stand for long periods of time and whose personal or family history may yield evidences of tuberculosis. Tender nodules develop in the deeper lay-

ers of the skin and in subcutaneous tissues. They are round or oval and are generally the size of a pea or larger. The color of the skin overlying the nodules varies from bright red to a purplish hue. In the course of several weeks the lesions become doughy and finally necrosis takes place, ending in ulcer formation. They heal very slowly, leaving permanent scars and pigmentation. The histologic picture shows tubercle formation with an inflammatory reaction and necrosis.<sup>9, 10</sup> The tuberculin reaction is negative in the majority of patients.

Treatment consists of rest in bed, elevation of the affected extremities, high vitamin and salt-poor diet, injections of tuberculin, and generalized as well as localized ultraviolet ray therapy. Roentgen therapy, especially of early lesions, is beneficial.

*Sarcoid of Boeck*.—The lesions of sarcoid of Boeck<sup>11</sup> may appear on the face, back, shoulders, or extremities. They vary in size from that of a pinhead to a dime. They may be single or multiple and are brownish red to purple in color. Slight elevation and smooth surface are constant findings. When the lesions disappear slight atrophic scarring might result.

*Sarcoid of Darier-Roussy*.—These lesions occur less frequently than the sarcoid of Boeck. They originate in the subcutaneous tissues.<sup>12</sup> The skin overlying the nodules may be normal or purplish. After several weeks or months they may break down, leaving ulcerated areas. They occur on any part of the body. Evidences of sarcoid appear in the lungs, long bones, and the lymph nodes. In fact, sarcoidosis may affect the viscera without cutaneous manifestations. The condition is seen in both tuberculous and nontuberculous subjects. The disease tends to heal spontaneously.

The systemic disease, sarcoidosis, is attracting

TABLE 2 —HEMATOGENOUS TYPES OF CUTANEOUS TUBERCULOSIS

Name of Disease	Clinical Signs	Histological Characteristics	Tuberculin Reaction
Acute miliary tuberculosis	Widespread purpuric or papular eruption occurring in terminal stage of general visceral tuberculosis	Tubercle formation and demonstration of tubercle bacilli in lesions	Negative
Lichen scrofulosus	Small pinhead-sized papular eruption appearing mainly on the trunk in children	Tubercle plus inflammatory process without necrosis occurring in the papillary zone. Process is superficial	Hypersensitive
Rosacea-like tuberculid of Lewandowsky	" " " "	Tubercles with inflammatory process	Hypersensitive
Papulonecrotic tuberculid	" " " "	Inflammatory process with necrosis without suggestion of	Hypersensitive
Erythema induratum of Bazin	Deep nodules and some ulcers occurring on dorsal aspects of lower extremities in young women. Lesions in different stages of evolution and involution	" " " "	Hypersensitive
Lupus miliaris disseminatus faciei	" " " "	Tubercles and inflammatory process simulating lupus vulgaris	Hypersensitive
Sarcoid of Boeck	" " " "	Tubercle formation primary in the cutis without any other pathologic process	Hypersensitive (positive reaction)
Sarcoid of Darier Roussey	Subcutaneous small nut-sized nodules. Sometimes they ulcerate. Usually found on extremities	Tubercle formation primary in the subcutis without any other pathologic process as in lupus pernio	Hypersensitive
Lupus pernio	Symmetric purplish lesions of face, nose, ears, toes, and fingers simulating frostbite. Sometimes ulcerations often associated with lupus vulgaris	" " " "	Hypersensitive

much attention. This condition has been repeatedly discussed in current articles. The subject is too complex for review in this brief communication. The reader, however, is advised to read the article on this subject written by Longcope.<sup>13</sup>

The histologic picture is the same in both the superficial and deep type of sarcoidosis. There is definite tubercle formation either in the cutis or in the subcutis. The tuberculin reaction is negative. As a rule, patients with sarcoid can tolerate stronger tuberculin dilutions than normal individuals.

The best results in the treatment of the Boeck and Darier-Roussey types of sarcoid are obtained with roentgen therapy. Arsenotherapy is also beneficial. In extensive and generalized cases the treatment for systemic tuberculosis should be instituted.

**Lupus Pernio**—The early lesions of lupus pernio are small nodules which appear where the circulation is terminal, namely, the tip of the nose, the pinnae of the ears, fingers, and toes. The lesions have a purplish color and many telangiectases are seen on the surface. Ulceration takes place early in the course of the disease. After healing scars result. This rare condition is aggravated by cold. It is sometimes found associated with lupus vulgaris, lupus erythemato-

sus, and scleroderma. Some even consider this to be a variant of Raynaud's disease.

The treatment consists in preventing infection of the ulcerated areas and in improving capillary circulation either by local means or by the use of vasodilators.

The purpose of this paper has been to review the various manifestations of cutaneous tuberculosis, their association with visceral tuberculosis, and the general therapeutic management of each variety.

To clarify some of the confusion that exists even among dermatologists in regard to the various tuberculodermas, it may be advisable to summarize this subject in tabular form (see Tables 1 and 2).

## AN EXPERIMENT IN READING MEDICAL LITERATURE

Some of the faculty members in the Medical School [Medical College of Virginia] have been interested in studying reading abilities of medical students. During the accelerated war program, speed of reading has become, more than ever, a problem. How fast do medical students read? Can they be made to read more rapidly? Do they really know how to read? These, and similar questions, were in the minds of these faculty members.

Last fall we constructed a test which we called "Exercises in Reading Medical Literature" and gave it to seventy-one freshmen. The first exercise was scored on the basis of the number of seconds it took to read it. Scores ranged from 40 to 140 seconds. The second exercise was scored on the basis of the number of words read in 40 seconds. The score range was from 70 to 303 words. For the 71 students the correlation between the two methods of measuring speed was  $0.86 \pm 0.02$  (Pearson Product-Moment Method). This indicates that either method of measuring speed is worth while.

Exercises III to VIII were more definitely concerned with comprehension of the content read, tested by multiple-choice and true-false items covering the content. While there were time limits, they were not unduly restrictive—i.e., each student had some opportunity to read at his own speed. Comprehension, therefore, was emphasized more than speed, whereas in Exercises I and II there was no measure of comprehension obtained. Correlations between Exercises I and II, and Exercises III to VIII combined, were, respectively,  $0.23 \pm 0.07$  and  $0.26 \pm 0.07$ . These low correlations, substantiating one another, supply definite evidence that speed and comprehension in reading medical literature are not closely related. The medical student who reads fastest is not necessarily the one who reads with comprehension. There are evidently other factors which operate in comprehension than speed alone. Neither can one say that the slowest reader comprehends better, for the correlations were positive—not negative.

A further suggested experiment is one where there are no rigid time limits on the reading—where the test is a power test of comprehension alone. Any reluctance to experiment in reading medical literature may be relieved if the instructional values of such exercises are considered.

The lecture method has become probably too much of a fixture in medical education—in all higher education, for that matter. It undoubtedly has its value, but its exclusive use is not justified by any objective measurements of its values. The writer

has often given expression to the thought that the lecturer is the one who probably gets most of the benefits from his lectures. While people generally seem to enjoy some lectures, there has never been enough measurement of the outcomes of lectures in medical schools, for example, to draw any valid conclusions concerning their effects. The writer would guess, from many years of contemplation and reflection, that often the outcomes from many lectures by professors to students are meager from the students' point of view. At least it is "up to the professors" to furnish valid and reliable measurements to prove the contrary. The reading-exercise method, with valuable reading material selected, supplies an alternative to the lecture method which may be tried on occasion anyway. It may prove to be an excellent method of instruction and has advantages of furnishing numerical data on student understanding and mental achievement as well. Why not give it a trial? It might prove itself so worth while that it would receive increasing emphasis in instruction.

Teaching by and through testing is a method which probably has not been stressed sufficiently. The measuring value of testing has been too exclusively emphasized. Certainly, there is inherent in the testing process a student motivation not always found in other methods of instruction.

While the lecture method—especially the lecture demonstration—is indispensable under certain circumstances, and especially in stimulating emotional attitudes, there are other methods which should be given experimental opportunity to prove themselves. The reading exercise is one. It might not even be necessary to have tests mimeographed.

Textbook materials might be utilized for the purpose. Preparing tests, mimeographing, and scoring are three objections to this method of instruction. The use of the regular text; a simple method of supplying queries—even the oral method might be utilized; and a quick and easy method of scoring the queries; these might overcome the objections usually raised against too much testing with the complaints arising in preparing, mimeographing, and boring time spent in scoring.

Is it not true that an instructor's function is partly one of instructing students how they may best get desired information from the printed materials available for his courses? The reading-exercise method is recommended for this purpose.—Arthur Willis Hurd, in *Journal of the Association of American Medical Colleges*, May, 1944

# TISSUE DOSE ESTIMATION IN COMBINED ROENTGEN AND RADIUM THERAPY FOR CARCINOMA OF THE UTERINE CERVIX

WILLIAM E. HOWES, M.D., Brooklyn

THE custom of stating radium dosage in milligram hours only is almost universal in gynecologic applications. Such terminology is, of course, inadequate to indicate the radiation energy delivered to any part of the pelvis. If all the factors are included in the designation, such as the location and size of the radium sources, the filtration, and radium content, then the dosage can be calculated to any location within its practical sphere of influence. This is best computed in gamma r. To properly evaluate dosage it is necessary to measure the amount of radiation delivered to the tumor and to the surrounding normal structures, so that adequate amounts be delivered to the tumor and careful determination made as to the radiation received by surrounding organs.

Carcinoma of the cervix is an epithelial new growth whose curability by radiation can be considered no greater or less than that of other epithelial tumors. To sterilize this lesion radiologically, the equivalent of eight to twelve erythemas must be delivered to all parts of the growth within three months. The spread of the neoplasm is by direct extension centrifugally, the earliest spread being usually in the parametric structures in the region of the paracervical triangle. In a high percentage of the cases there is a coincident spread to the surrounding lymph nodes, among which is included the obturator node, which is located within 1 cm. of the lateral pelvic wall on a level with the cervix. The combined x-ray and radium therapy must therefore be directed not only to destroy carcinoma in the cervix but to a large circumferential zone which for the purposes of this paper may be considered as a spheroid 10 cm. in its horizontal diameter and 5 cm. in its vertical diameter. To evaluate the results of therapy it is therefore obligatory to calculate radiation energies not only to the center but also to the periphery of this vulnerable zone. Normal structures in the pelvis must also be guarded from over-irradiation.

At the Brooklyn Cancer Institute radium dosage is calculated in gamma r. This is computed for all surface, interstitial, and most intraluminal applications in accordance with dosage tables as published by Paterson and Parker,<sup>1</sup> Quimby,<sup>2</sup> Laurence,<sup>3</sup> and Wolf.<sup>4</sup> However, the anatomy of the vagina and the cervical and uterine canals does not lend itself to any

such configuration of the radium sources that such tables can be used as a basis of calculation.

Arneson<sup>5</sup> and Nolan<sup>6</sup> have presented a computation of distribution of radium dosage measured in erythemas for various radium arrangements within the uterus and vagina. Sandler<sup>7,8</sup> and Tod<sup>9,10</sup> have attacked the problem differently and have made definite measurements in gamma r as delivered to certain fixed points. This same method has been followed by Tenahan,<sup>11</sup> using interstitial radium needles. To meet this problem at the Brooklyn Cancer Institute it was decided to measure the gamma r delivered to the cervix and to certain theoretic fixed points in the pelvis for two specific geometric configurations of the radium sources such as the tubes might be arranged in suitable cases (Figs. 1 and 2).

A diagram of the radium tubes so located was drawn up (Figs. 1 and 2) and the following points chosen for measurement:

A—a point 2 cm. lateral to the center of the lower radium tube in the cervical canal. This is calculated as just lateral to the cervix at the base of the broad ligament and marks the nearest point of the crossing of the uterine artery and the ureter. This is designated as the paracervical triangle and represents the most sensitive location in the pelvis as to limitation of tolerance of normal structures to radiation (Tod<sup>9</sup>).

B—a point 5 cm. lateral to the interspace between the lower two tubes in the cervical and uterine canal and represents the position of the obturator node located within a centimeter of the lateral pelvic wall. Point B may also be thought of as a focal point within the lateral extension of the broad ligament. This is called the lateral pelvic wall.

C—a point  $1\frac{1}{2}$  cm. below the tip of the lower tube in the cervical canal and at the apex of the circumference of the central cork within the vagina. This represents the external os and is called the cervix.

D and E—points  $2\frac{1}{2}$  cm. anterior and posterior to the junction between the lower tubes in the uterine canal, designated as bladder, D, and rectum, E. The bladder and rectum are, of course, large mobile organs. D and E were computed as theoretically representing some near point in their wall and the dosage computed should therefore be con-

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, May 6, 1943.

ANTERO-POSTERIOR VIEW

LATERAL VIEW

## RADIUM DOSAGE DISTRIBUTION

FIG. 2

lateral vaginal walls, gradually spreads during the period of application, as shown in Fig. 2.

Such a stereotyped setup as a basis for computation of gamma  $r$  is therefore fraught with many inaccuracies. Such a plan does, however, represent a workable method of computation of gamma  $r$  which is being carried out in clinical practice at the Brooklyn Cancer Institute. It is understood that the gamma  $r$  so estimated represent a relative indication of dosage delivered and can in no way be considered as an absolute measurement. Every effort is being made to increase the accuracy of these measurements.

### X-Ray

A depth dose graph is drawn up from actual

measurements of each patient treated in the x-ray department. All roentgen dosage at the skin is planned secondary to determination of a specific tumor dose (Camiel<sup>12</sup> and Howes<sup>13</sup>). With this graph and the radium chart as described, it is possible to compute the  $r$  delivered to specific points within the pelvis as delivered by roentgen and gamma rays. This paper is presented to illustrate such a method of computation as carried out at the Brooklyn Cancer Institute.

*Technic of Usual X-Ray Therapy.*—Most pelves are divided into six ports, three anterior and three posterior. Each field extends from the crest of the ilium to the pubis and is of sufficient width to include most of the anterior and posterior circumference of the pelvis without

(0.5 Mm. Pt Filtration—See Fig. 2)

Tube No.	A Para-cervical Triangle	B Lateral Pelvic Wall	C Cervix	D Rectum or Bladder
1	0.27	0.23	(0.20)	0.46
2	0.90	0.31	(0.49)	1.07
3	1.92	0.31	(3.42)	1.07
4	0.74	0.18	3.75	0.55
5	1.92	0.32	3.75	0.55
Total	5.75	1.35	(11.61)	3.70
Average	1.15	0.27	(2.34)	0.72

Correction factor for 1.0 mm. Pt = 0.90.

Correction factor for 1.5 mm. Pt = 0.80.

The above radium dosage distribution calculation was made by C. B. Braestrup, using the dosage tables computed by Bernard S. Wolf, M.D.<sup>4</sup> (Radium Dosage Tables).

overlap, usually 10 by 15 cm. The target skin distance is constant at 50 cm. A ray quality whose half value layer is 1.8 mm. Cu is used. The radiation equivalent of 200 r as measured in air is delivered to each of two ports daily. The areas are so rotated that three treatments are required to completely circle the pelvis. The hips are raised higher than the shoulders, so that some of the pelvic loops of the ileum may gravitate above the fields of radiation. The roentgen cycle is usually divided into two parts, as when sufficient x-ray therapy has been completed to deliver 4,500 r to the parametria, contracture of the vaginal vault and cervical canal results. This may force modification of the originally planned radium setup.

### The Technic of the Radium Insertion

Three radium tubes are tied in chain formation within a thin-walled rubber sac. These are inserted the length of the uterine and cervical canal, the lowest tube being located just above the ex-

ternal os. An arm of the colpostat is then pressed into each lateral vaginal fornix. Whenever possible a cork is placed between, up against the vaginal surface of the cervix. The rectum and bladder are packed away with plain gauze. When six 10 mg. tubes are used they may be left *in situ* for one hundred hours. This gives a total of 6,000 milligram hours, or if 15 mg. tubes are used the time interval is generally reduced to approximately sixty-seven hours.

### Computation of Gamma r

The gamma r delivered to the five predetermined points are computed from Table 1. Thus with six tubes of 10 mg., located as drawn in Fig. 1, the following computation is made: The total for each column is multiplied by 10, as each tube contains 10 mg., and this by 100, as

TABLE 4.—COMPUTATION OF X-RAY DOSAGE  
Large Pelvis—Diameter = 23 Cm. (Moderate Compression)

Port I	13	31.0		
Port II	3.5	110.0		
		141.0 × 30 = 4,230 r		
Cervix				
Port I	10.5	46.6		
Port II	11.0	43.4		
		90.0 × 30 = 2,700 r		

FIG 3A Roentgenograph of location of radium sources in the uterus and vagina. Immediately after application

FIG 3B Ninety-six hours later. Note the spreading of the arms of the colpostat

each tube is left *in situ* one hundred hours, this result must be multiplied by the correction factor, representing the filtration, which is, in this instance 1 mm P+. Thus the gamma r delivered are shown in the following graph

(Dose in milligram hours = 6 000)

A	B	C	D and E
Paracervical	Lateral Pelvic Wall	Cervix	Bladder and Rectum
6 410	1 640	14 340	4 020
$\times 0.9$	$\times 0.9$	$\times 0.9$	$\times 0.9$
5 769	1 476	12 901	3 618

If tubes of 15 mg. each had been used and the time reduced to sixty-seven hours the milligram hours would be the same, but these 15 mg. tubes have an increased filtration—namely, 1.5 mm platinum—and therefore the correction factor will be 0.8 and the computation will be as follows

(Dose in milligram hours = 6 000)

A	B	C	D and E
Paracervical	Lateral Pelvic Wall	Cervix	Bladder and Rectum
6 410	1 640	14 340	4 020
$\times 0.8$	$\times 0.8$	$\times 0.8$	$\times 0.8$
5 128	1 312	11 512	3 216

FIG 4 Schematic cross section of pelvis 16 cm in diameter

FIG 5 Schematic cross section of pelvis 23 cm antero-posterior diameter (with compression)

This illustrates the reduced dosage delivered when increased filtration is not compensated for by increase in radium content or time

The error, of course, is much larger in computing gamma r with different radium setups

For instance, if the uterine canal is short and will accommodate but two radium tubes and the vaginal vault is so small that only two arms of the colpostat can be inserted, the following method of computation is used

The total gamma r delivered by these four tubes can be estimated by eliminating Tube 1 from Table 2 and multiplying the totals for each anatomic location by the number of hours of application—i.e., 100, and by the strength of each tube—i.e., 15 mg

(Dose in milligram hours = 6 000)

A	B	C	D and E
Paracervical	Lateral Pelvic Wall	Cervix	Bladder and Rectum
8 220	1 680	17 115	4 860
$\times 0.8$	$\times 0.8$	$\times 0.8$	$\times 0.8$
6 576	1 344	13 692	3 888

TABLE 5.—COMBINED X-RAY AND RADIUM DEPTH DOSE

Small Pelvis—Anterior-Posterior Diameter = 16 Cm. Estimated Total			
	X-Ray	Radium*	Erythemas
A Paracervical triangle (parametria)	4,500 r	5,800 gamma r	13
B Lateral pelvic wall (parametria)	4,500 r	1,500 gamma r	8½
C Cervix	2,500 r	13,000 gamma r	17
D Bladder	3,100 r	3,600 gamma r	8½
D <sup>1</sup> Rectum	3,300 r	3,600 gamma r	9

Estimated to nearest 100 r.

X-ray—quality HVL 1.8 mm. Cu., 600 r per erythema.

Radium—1,000 gamma r per erythema.

\* Six 10 mg. tubes 1 mm. Pt, 100 hours.

From this computation it appears that for a given total dose two radium sources in the uterus plus two sources in the vagina will deliver a greater total dose to the cervix and paracervical triangle with an equal gamma r equivalent to the lateral pelvic wall as compared with the three sources in the uterus and in the vagina.

The time table, which is of course significant in determining the abilities of the surrounding structures to withstand a large dose of radiation, would then be as follows: The first half of the x-ray cycle is delivered within three weeks; the radium is then placed *in situ* for from three to four days; this is followed by a one month's interval to permit the intensity of the radium reaction to subside before the final course of x-ray therapy is added. Such an outlined course of therapy will consume from three to four months.

To further illustrate this method of depth dose computation, two pelves have been sketched: one relatively small pelvis measuring 16 cm. (Fig. 3) in its anterior-posterior diameter and one larger pelvis measuring 23 cm. after moderate compression (Fig. 4). The tissue doses delivered to the cervix, bladder, and rectum are computed when 4,500 r have been delivered to the parametria. This takes for granted that the parametria on each side have been crossfired by four ports, and the cervix, bladder, and rectum, being in the midabdomen, by two ports only (Tables 3 and 4).

To this has been added the radium dosage as computed in gamma r to these same structures.

TABLE 6.—COMBINED X-RAY AND RADIUM DEPTH DOSE

Large Pelvis—Anterior-Posterior Diameter = 23 Cm. Estimated Total			
	X-Ray	Radium*	Erythemas
A Paracervical triangle (parametria)	4,600 r	5,100 gamma r	13
B Lateral pelvic wall (parametria)	4,600 r	1,300 gamma r	9
C Cervix	2,700 r	11,500 gamma r	16
D Bladder	3,700 r	3,200 gamma r	9
D <sup>1</sup> Rectum	4,200 r	3,200 gamma r	10

Estimated to nearest 100 r.

X-ray—quality HVL 1.8 mm. Cu., 600 r per erythema.

Radium—1,000 gamma r per erythema.

\* Six 15 mg. tubes, 1½ mm. Pt, 67 hours.

The gamma r to the paracervical triangle, bladder, and rectum are so calculated as to represent the largest amount these structures would receive by measuring to their nearest point. For final analysis these doses are transposed into erythema equivalents. The erythema for the roentgen ray is taken as 600 r and for the gamma ray 1,000 r. The erythema equivalent for both radiant sources has then been calculated for these two pelves (Tables 5 and 6).

### Summary

Tissue dosage estimation in combined roentgen and radium therapy for carcinoma of the uterine cervix as carried out at the Brooklyn Cancer Institute is described.

### POSTWAR BREAKDOWNS

The greatest number of breakdowns will be observed among the men who come back after the war is over. One should imagine that heroes on land, on the sea, and in the air, who have gone through all the horrors of modern warfare, should be able to

play with the demands of a peaceful life as easily as a Chinese juggler with his sticks. 1918 proved without doubt that it is easier to be heroic than to be courageous.—L. Sicher, M.D., in *Med. Woman's J., Mar., 1944*

# THE ROLE OF MOTIVATION IN PSYCHOTHERAPY\*

LEWIS R. WOLBERG, M.D., Kings Park, New York

SOONER or later during psychotherapy the physician is confronted with the motives underlying the patient's desire for treatment. These motives are vastly more important in emotional illness than in physical disease, for they have a determining effect on the duration of therapy as well as on the possibilities of cure.

There are many reasons why a person with an emotional problem seeks psychotherapy. By far the most common reason is to alleviate the suffering associated with his illness. Usually he has already run the gamut of sedatives, tonics, endocrines, and placebos in a desperate search for relief. In psychotherapy he believes he has come to the end of his rope, and while he ardently wishes to liberate himself from his suffering, an attitude of hopelessness may permeate his outlook. Nor can he be entirely blamed for his skepticism. Psychotherapy to him is a nebulous phenomenon that defies his sense of logic. How talking with the physician can possibly have an ameliorative influence on his stomach complaint, fatigue, phobias, and other symptoms is beyond his comprehension. He may even regard the physician's failure to prescribe medications as a sign that his complaints are considered imaginary. Consequently, at the earliest possible time, it is urgent for the physician to show him that his suffering, though significant, is merely the currency with which he pays for his neurosis, and that more basic issues are involved, such as his relationships with people and faulty attitudes toward life.

We may take as an example the phenomenon of tension, which is one of the most universal symptoms in neurosis. Tension is a manifestation of disturbed homeostasis and is associated with powerful excitations which reach the nervous system at various levels of integration—visceral, somatic, and psychic. The excitations serve a biologic function, mobilizing the physical and psychologic resources of the individual to restore homeostasis. In normal persons tension stimulates behavior patterns of an adaptive nature directed toward the gratification of unfulfilled vital needs. In neurotic persons, on the other hand, techniques of adaptation are so inadequate that they are unable to gratify biologic and social needs, and the individual is as a result diverted from goals consistent with his best interests. Furthermore, the neurotic substitutes for normal

goals compulsive drives for power, perfectionism, dependency, detachment, or masochistic surrender, which make inordinate demands on himself and on others and eventually alienate him from the world. His drives serve a spurious safety function and failure to satisfy them will contribute vastly to his state of tension.

The visceral manifestations of tension result from massive stimulation of the autonomic nervous system by way of the hypothalamus. Changes are wrought throughout the smooth musculature and internal organs of the body. Among the more common symptoms are esophageal, diaphragmatic, and gastrointestinal spasms, hyperchlorhydria, altered tonus of vessels with changes in the blood distribution throughout the body, abnormal stimulation of the heart, bladder, and genitalia, and a lowered threshold to sensory stimuli resulting in paresthesias, hyperesthesias, and functional disturbances of the higher sensory organs. In certain predisposed individuals visceral changes of an irreversible nature may occur in the form of psychosomatic illness. The effect of tension on somatic centers produces an increased tonus of the striated musculature with "neuromuscular hypertension," spasms, and ties. Excitations of tension stimulate the psychic apparatus, probably by way of the corticohypothalamic pathways, producing subjective feelings of inner distress and a symbolic representation of tension in the form of obsessive, phobic, and hypochondriacal thoughts.

Tension states are so bound up with the general adjustments of the individual to life that mere treatment of the physical manifestations of tension can have but a palliative effect. Eventually, through psychotherapy, the patient realizes this and is brought to the understanding that his original motive for treatment, namely, the alleviation of his distress, must be replaced by the motive of understanding the causes of his suffering. He may, for example, become increasingly aware of how he makes unreasonable demands of people in authority, clinging to them in a dependency relationship, subjecting himself to self-abasement and submission to insure his being protected and loved. He may discover that he harbors bloated ambitions to a point where even normal accomplishments are signs of mediocrity and failure. Or he may gain insight into how in a close interpersonal relationship he feels threatened and strives to remove himself from people by steering a course of com-

\*From the Department of Psychiatry, the New York Medical College, Flower and Fifth Avenue Hospital.

\*A second paper by Dr. Wolberg, "Goals and Objectives of Psychotherapy," will appear in a later issue.

pulsive independency, isolation, and detachment. In short, he may discover that because of inimical experiences in his early life he has developed trends oriented around desires for power, dependency, isolation, prestige, superiority, perfectionism, unobtrusiveness, or self-devaluation—trends which inevitably bring him into conflict with the world and with other individuals. He may see how his disorganized relationship with the world which initially fostered the development of neurotic trends is reinforced by the very pursuit of his trends. He may even come to an understanding of how his trends inevitably lead to feelings of helplessness by undermining his self-esteem and to the generation of tension by vitiating his basic needs.

Yet the realization that suffering results from an exploitation of his neurotic trends is not in itself a sufficient incentive to motivate the patient to abandon them. Usually he will cling to his drives in spite of his suffering and with full insight of what he is doing to himself. Indeed, it becomes increasingly clear that the fulfillment of his trends, destructive as they are, is the moving principle of his life. An untrained observer may consider his aims useless or foolish or inconsequential, but if one analyzes the deep meaning of neurotic drives one can discern in them a vicarious means to security, affection, and self-respect. The neurotic person seeks from life things that every human being wants and needs, such as companionship, love, assertiveness, and creative self-fulfillment, but unlike the normal person he feels so vulnerable within himself that he can attain these goals only if he renders himself so powerful or so dominant or so compliant or so good that he cannot be injured in his relationships with others. The particular drives that he pursues protect him from hurt and render it possible to gain at least part of the gratifications essential to living. To remove these is a dual threat, for he feels he will be exposed to injury and will lose the only technic he knows to secure for himself essential wants. Eventually, of course, his drives interfere with his relationships with people and maneuver him into a position where he feels humiliated, exploited, and in jeopardy of being hurt. They even isolate him from his own biologic impulses. Nevertheless, they wield an unreasonable influence over him and the patient cannot be expected to part with them until he has learned new ways of adjustment.

As a matter of fact, when he first becomes aware of how suffering is an inevitable consequence of his neurotic goals, he will seek from the physician a formula whereby he can indulge his drives without paying the penalty of suffering. He will somehow imagine that his failure

to utilize his neurosis successfully is due to an error in himself and he will want the physician to correct this error, believing that when this is accomplished he will soar upward, performing in ways not merely godlike, but even better than God. His chief motivation then is not to abandon his neurosis but to find out better ways to make it work.

It may be many months before the patient is fully cognizant of how enmeshed he is in the contradictory tangles of his trends. Considerable work may have to be done before he can recognize within himself normal biologic and social promptings which he has repressed because he has associated them with fantastic fears of injury or danger. Even more work will be needed before he acknowledges that a gratification of these promptings is within his reach without first having to employ ingratiating, self-punitive, withdrawing, or domineering tactics as embraced in his compulsive drives.

Before this can be accomplished, however, it is essential to effect a transition in his motivations from the mere alleviation of suffering or the bolstering of neurotic defenses to the ability to enter into cooperative relationships in which he feels neither threatened, unloved, open to criticism, challenged, or driven to domineer or intimidate. Three aspects are involved in this reintegration of motives, and these include his attitudes toward people in general, toward authority, and toward himself.

The neurotic individual's attitudes toward the world and toward people are poisoned by destructive experiences in his past. He may have been disappointed in his strivings for love and security. He may have been crushed in the development of assertiveness or in his evolution as an independent being. As a result, he is at the mercy of catastrophic feelings of helplessness, unworthiness, vulnerability, and lowered self-respect. To overcome these feelings he has found it essential to develop subterfuges to defend himself against a potentially hostile and menacing world. His relationships with people involve a conviction that he will be hurt or humiliated or disappointed, and he employs many defenses to protect himself from harm. In his relationship with the physician he is bound to develop the same type of attitudes and defenses, but as he discovers through interpretation the meaning of his defenses he may eventually see that while at one time they served a protective function, they no longer serve a purpose in his present relationships.

The second essential motivation is associated with a wholesome attitude toward authority. Every person possesses within his conscience a compulsive set of attitudes patterned after the

prohibitions and injunctions of his parents. The conscience of the neurotic person is usually hypertrophied and tyrannical and punishes him for impulses and strivings of a relatively normal nature. It is almost as if there resides within himself a parental representative who threatens him with the loss of love or with physical injury for the slightest transgression. To avert fancied hurt he may subject himself to inordinate disciplines and he may feel obligated to repress basic needs and impulses. He will transfer these attitudes to all symbols of authority toward whom he may act in an ingratiating, submissive compliant manner, burning inwardly with resentment which he dares not express because of fear of counteraggression. On occasion he may turn his hostility on himself and succumb to depressive or psychosomatic symptoms, or when his hostility becomes overwhelming, or when he momentarily dissolves his conscience in drink, he may explode in acts of destruction or violence with aftermaths of guilt and self-recriminations. Mental health is associated with a reorientation in his attitudes toward authority to a point where he no longer considers himself at the mercy of a menacing overlord who can manipulate or murder him. In addition he must liberate himself from the tyranny of his conscience, which has hitherto put an embargo on the most reasonable needs and demands.

The third essential motivation is the ability to be expressive and self-assertive. Involved are tolerant attitudes toward one's impulses and desires. An undermined self-esteem is one of the most basic constellations found in the neurotic individual and expresses itself in feelings of inadequacy and worthlessness toward oneself, one's capacities and functions. Often self-contempt is so deep and unconscious and its avowal so disastrous to the integrity of the individual that it is disguised by strivings for self-admiration or perfectionism or by arrogant notions of one's capacities and significance. Lowered self-esteem is important as a source of tremendous tension, since a healthy regard of the self is essential to the security feelings of the individual. A devaluated self-regard renders the person sensitive to the slightest frustration, because every rebuff or obstacle is interpreted by him as evidence that he is helpless and contemptible. Furthermore, the undermined person is tremendously vulnerable and constantly obsessed with the feeling that he cannot be loved for himself, but rather will be loved in proportion to how well he performs or obeys or distinguishes himself.

Before mental health can be assured it is necessary that the person be motivated toward a healthy estimate of himself as an individual with a right

to express his basic wishes and urges without fear of disastrous consequences.

Development to a state where the patient has a spontaneous wish for better relationships with people, with the world, and with himself is a mark of tremendous progress in personality growth. In itself it is an index of the abandonment of neurotic goals. It usually comes about only after much treatment. It is necessary to regard with great caution any premature declaration on the part of the patient that he seeks to throw aside all his compulsive trends, for this may be nothing more than an appeal for approval and an attempt to distract the physician from probing into more neurotic motivations. The real test lies not in vociferous utterances, hopes, and promises, but in the carrying out of his new motivations in behavior and in the expression of his needs and impulses in action.

### Summary

The motives that determine the patient's desire for psychotherapy are tremendously important, for so long as he clings to inadequate or neurotic motivations little progress in treatment can be expected. In most cases the chief motivation is to escape suffering and to eliminate symptoms that the patient senses are destructive to himself and others. Suffering is at first considered an isolated experience and is rarely related to existing neurotic character trends. After a period of treatment the individual becomes conscious of the fact that his symptoms are consequences of his particular attitudes toward life. He may become aware of the fact that his neurotic drives oppose basic biologic needs, that they involve contradictory and conflictual strivings, or that they are insatiable and make unfair demands on himself and others. Gradually he may see that suffering is inescapable so long as he pursues his trends. This insight in itself is not sufficient to create change, but it may provide the incentive to investigate the nature and consequences of his trends.

At the same time that the patient desires change he will resist it vigorously because his defenses are as essential to him as life itself. As psychotherapy proceeds he gradually will become conscious of the fact that there are other motivations in life perhaps more gratifying than those which are embraced by his neurotic trends. He may, for example, become cognizant of the fact that there are other techniques than those he knows for the attainment of essential needs which do not involve internal contradictions and do not terminate inevitably in suffering. As his values reorient themselves his motivations will change toward strivings consonant with mental health. These involve the ability to relate himself co-

operatively with people and include the re-establishment of harmonious attitudes toward authority and toward himself. The dynamic effect of a change in motivations is to release the individual from the tyranny of his conscience, permitting him to express his basic biologic and social goals without fear of injury or the loss of love, enabling him to be self-assertive and creative in keeping with his abilities and aptitudes.

Words themselves will not bring the patient around to an abandonment of neurotic motivations and to an acceptance of those essential to mental health.

It is by experiencing a new attitude toward people in the interpersonal relationship with the physician that the patient will realize that it is not necessary to exploit his neurosis to get that which he wants from life.

## REVISION OF NATIONAL FORMULARY PLANNED

Deletion of nearly a third of the drugs in the *National Formulary* and acceptance of about 115 new monographs were among the extensive changes approved by the Committee on National Formulary at its three-day session held recently at the American Institute of Pharmacy, Washington, D.C. Developmental work on *N. F. VIII* is now under way, and the new edition is expected to be on the pharmacist's reference shelf by the end of 1945.

The use of English instead of Latin for primary drug titles was one of the basic changes of policy authorized. This action, which overthrows a long-standing tradition in pharmaceutical compendia, was taken as a step toward greater rationality in drug nomenclature and, in the opinion of the Committee, is in conformity with the trend of modern medical science and prescribing. Latin will be retained as the secondary title, appearing in smaller type and occupying the place of present English titles.

The composition and nature of *N. F.* drugs will be indicated in the titles to the greatest extent possible. Drugs dispensed under *N. F.* synonyms must also meet the official standards.

Metric doses will be given greater emphasis in the new edition. Consideration was given to a proposal to drop apothecaries' doses completely, but the Committee felt that the steady trend toward the use of the metric system had not yet reached the

point where apothecaries' doses could be safely omitted from the monographs.

Discussion later centered on enteric-coated medications, since some of those now being dispensed do not dissolve in the intestinal tract. Apparently standards will not be developed in time to include enteric coatings in the forthcoming revision but the Subcommittee on Solid Preparations for Internal Use is at work on the project.

Extension of another basic policy of the Committee will make *N. F. VIII* more self-contained, thus obviating the necessity of looking up information in the *Pharmacopoeia* in connection with *N. F.* procedures.

Changes in formulas brought about by the exigencies of war will not be included in the regular revision. Instead they will be maintained on a temporary basis in a special supplement to be issued concurrently with *N. F. VIII*.

Recognizing the value of official standards to the practicing pharmacist as a means of providing dependable drugs and useful dispensing information, the Committee on National Formulary, composed of representatives of the nation's pharmacists, is inviting each state pharmaceutical association and individual pharmacists to participate in the revision work in an advisory capacity. Comments concerning the list of deletions and admissions tentatively planned are invited.

## BIOLOGICAL PHOTOGRAPHIC ASSOCIATION WILL MEET IN BINGHAMTON

The Biological Photographic Association will hold its fourteenth annual meeting on September 7, 8, and 9 in Binghamton, New York. Papers will be presented by experts in the fields of still and motion picture photography, photomicrography, etc. Round-table discussions will be scheduled for the exchange of ideas and methods. A salon of pictures made by leading biologic photographers from all over the country will be an important feature of the meeting, and representatives from firms specializing in precision equipment will demonstrate their products.

The Binghamton meeting will offer members and their guests an opportunity to visit Ansco, manufacturer of photographic materials. The Ansco color process will be demonstrated, and a new color printing method will be described which permits the making of color prints directly from color transparencies in one exposure step. A paper will be

given by Dr. Bruce Buckler, Director of Visual Education of International Business Machines Corp., concerning modern technic in the preparation of visual aids.

The Biological Photographic Association is a non-profit organization for the study of photography as applied to medicine, dentistry, and the biologic and natural sciences. Its members are scientific photographers, scientists who use photography in their work, and amateurs with a deep interest in biologic and medical photography. The *B. P. A. Journal* is published quarterly, constituting a volume of about 250 pages, which is furnished free to members.

Further information about the Association and the Convention program may be obtained by writing to the Secretary of the Biological Photographic Association, University Office, Magee Hospital, Pittsburgh, Pennsylvania.

# THE ABUSE OF VASOCONSTRICTORS IN HAY FEVER AND VASOMOTOR RHINITIS

LOUIS STERNBERG, M.D., New York City

WITH the introduction of epinephrine, ephedrine, and numerous related synthetic compounds into the pharmacopoeia, the use of nasal vasoconstrictors began to multiply. Not only are they now often prescribed by physicians, but are also sold readily behind the drug counter directly to the patient.

Gray<sup>1</sup> and Negus<sup>2</sup> state that ciliary motility is greatest when the pH range is at 8.2-8.6, and then slows down in slightly acid solutions when the pH is at 6.5 or less. Fabricant<sup>3</sup> finds that a medicament is more bactericidal when slightly on the acid side. The same author also quotes Stark,<sup>4</sup> who has shown that isotonic solutions are less irritant to the mucous membranes.

Vaughan,<sup>5</sup> Rackemann,<sup>6</sup> and Turner<sup>7</sup> suggest the use of vasoconstrictors in hay fever and vasomotor rhinitis, but do not mention contraindications to their use. Ballenger and Ballenger<sup>8</sup> find that a 1 to 3 per cent ephedrine solution does, in very rare instances, cause irritation and sneezing in vasomotor rhinitis. Barnhill<sup>9</sup> observes that cocaine and ephedrine often increase the severity of hay fever symptoms. Hansel<sup>10</sup> believes that the prolonged use of nasal sprays may increase the sensitivity of the mucous membranes. Scarano<sup>11</sup> finds that the continued use of ephedrine and benzedrine may create secondary reactions of "atony, returgescence, and bogginess of the nasal mucous membranes." Urbach<sup>12</sup> claims that vasoconstrictors occasionally exacerbate symptoms of hay fever instead of relieving them. Cooke<sup>13</sup> suggests ephedrine in a 1 per cent spray for the symptomatic relief of hay fever, but cautions against too frequent and prolonged applications. Grove<sup>14</sup> holds the same opinion. King and King<sup>15</sup> claim that "shrinking solutions are harmful to some patients" and that they are being overused.

During the past six years a number of patients have come to my attention whose nasal discharge and obstruction were definitely more the result of the abuse of various vasoconstrictors than of the underlying vasomotor rhinitis or seasonal hay fever. It appears that the allergic mucous membrane becomes refractory when in frequent and prolonged contact with these drugs for a variable period of time (three to five days), and then remains waterlogged no matter how often the vasoconstrictor is reapplied. At other times

those membranes become irritated and inflamed from the same cause. On and off a combination of these two phases can also be the result of sustained application of a vasoconstrictor. Not only is the patient at this stage not relieved from his distressing symptoms of hay fever or vasomotor rhinitis, but he now begins to feel the effects of the overdose of his drops that were meant to give him relief. Injury is added to insult and suffering and discomfort is the result.

## Case Reports

The following case histories will illustrate my point.

*Case 1.*—Mrs. I. D., 46 years old, has been suffering from seasonal and nonseasonal hay fever for three years. She had lost her sense of smell and taste for the past ten months. She came in on October 30, 1938, with a vial of nose drops that were sold to her by a druggist during August, when she suffered a great deal. She had been using these drops every hour for the past few weeks to relieve her nasal obstruction, and had to get an ounce bottle every second day to get momentary relief. It seems that very little of the drug was absorbed, for she had no constitutional symptoms in spite of the large dose she was using daily. On physical examination, her nose was found to be obstructed, and the mucous membranes were waterlogged and markedly inflamed. Skin tests were positive to house dust and ragweed. She was advised to give up her drops, and her relief was marked within one week.

*Case 2.*—J. R., 34 years old, a baker by occupation, was seen in March, 1943, with a history of sneezing all year round. His physician had given him drops about a month before, which he applied in his nose every few hours, but instead of being relieved, his condition became much worse. On physical examination the nasal mucous membranes were moderately edematous but markedly inflamed. No pus and no polypi were seen. There were positive skin reactions to wheat, corn, and rye. Symptoms improved 75 per cent upon the elimination of the drops. He was unable to give up his occupation, and is being treated with an extract of the offending inhalants.

*Case 3.*—Miss J. M., 21 years old, came in on August 18, 1943, with a history of early hay fever and pollen asthma. Her skin was sensitive to timothy and plantain, but it was negative to ragweed.

Her physician prescribed ephedrine drops, which she had been using since June. Usually in August she had been relieved of her symptoms, but this year in spite of the "constant use of the medicine"

From the Department of Allergy, Beth Israel Hospital. Presented before the Beth Israel Clinical Society, February 2, 1944.

every few hours, her suffering was intense. On physical examination her nasal mucous membranes were found to be waterlogged. Keeping her nose free from the drops for five days completely relieved her of her nasal complaint.

These case histories can be multiplied many times—and each one the result of the promiscuous use of a vasoconstrictor. These drugs may have their place in acute sinusitis or acute rhinitis, when used for a day or two only, but when indicated in vasomotor rhinitis or seasonal hay fever, they should always be used with discretion. Personally, I prescribe them very rarely, and only when the suffering of the patient is marked. They are then used as a spray in an atomizer, and never applied as drops into the nasal chambers. The patient is always warned of the danger of overdose. They are sprayed into the nose before retiring or during the early morning hours, because symptoms in these patients are usually most distressing then. For if drops are applied into a waterlogged nose while the patient is reclining, the drug will keep on its irritating effects for hours while the patient is in that position. In the spray very little of the drug is used up with each application, and it is also dispersed over a bigger surface at the same time.

Thirty-two of these patients were observed and followed up during the past six years. They used a total of eleven different vasoconstrictors. Of these, nine were in an aqueous solution of an average 1 per cent strength. One had an oily base and also contained camphor, eucalyptol, and menthol. Most of the preparations were isotonic, or approximately so. Since the pH was not indicated upon any of these vials, direct communication with the manufacturers revealed that most of the preparations were slightly acid—pH 4.5–6.5. One was neutral, another slightly

alkaline—pH 7.2. These values are subject to changes dependent on the age and the condition of the preparation. There was no evidence as to which vasoconstrictor did most of the damage. It was only a question of how long, how frequently, and how persistently the drug was applied in order to cause its insult.

### Summary

1. Vasoconstrictors should be applied with discretion when indicated as palliative measures in vasomotor rhinitis or seasonal hay fever.

2. They are to be used as a spray only, and not in the form of nose drops.

3. They should be applied once or twice at most during the twenty-four hours, and saved for the period of the day when symptoms are most severe.

## CHEMICALS OF TUBERCULOSIS EXHIBITED AT YALE

A collection containing more than three hundred chemicals made solely from the bodies of tubercle bacilli, and representing seventeen years of research under the direction of Dr. Rudolph J. Anderson, professor of chemistry at Yale, has been placed on permanent exhibit in the Sterling Chemistry Laboratory at Yale.

Dr. Anderson's epoch-making work has been done in cooperation with other institutions, including Columbia University and Rockefeller Institute.

Further experiment may make it possible to train white blood cells to digest parts of the tubercle bacillus which the phagocytes are normally unable to assimilate. Dr. Anderson's studies have shown that certain parts of the germs, particularly those known as phosphatides, resist the white blood cells,

and this is one reason why tuberculosis is a stubborn disease.

In a discussion of his subject when the exhibit was formally presented to the Sterling Laboratory on February 3, Dr. Anderson remarked, with characteristic frankness, that there is no human use for this idea at this time, and, although heartening experiments have been conducted on animals, how it is to be applied to human disease cannot be stated now.

The exhibit was presented to Yale University by the National Tuberculosis Association, under whose auspices the work has been done, and the new chemical substances represented in the exhibit open new fields of study in chemistry and offer an opportunity for advancement in therapeutics, the value of which cannot be forecast.—*Connecticut State M. J.*, March, 1944

# Case Report

## THE ADRENAL CORTEX IN MYASTHENIA GRAVIS

R. PIETRI, M.D., New York City

IN JULY, 1940, Moehlig<sup>1</sup> reported a case of myasthenia gravis that had a prompt remission following the implantation of de-oxyecorticosterone acetate pellets (hereinafter to be designated as "d.a.>").

In November of that same year I buried 450 mg of d.a. in the subcutaneous tissues of a colored patient who had been under treatment for some time. The improvement obtained was prompt and clear-cut, leaving no doubt in my mind at the time that it had been brought about by the hormone. Unfortunately, there were no preliminary studies made on this patient for the purpose of determining adrenal function.

Four other cases that came under observation subsequently were given the benefit of these studies and the results are analyzed below. All four failed to show any impairment of adrenal function as determined by the Cutler, Power, and Wilder<sup>2</sup> test. One case (Case 2) reacted poorly to high sodium chloride intake and two cases (Cases 2 and 3) were thrown into crisis by the injection of d.a. subcutaneously. Two cases (Cases 4 and 5) showed no response, favorable or unfavorable, to the high salt diet or to the injection of d.a. One case (Case 2) showed no effects, deleterious or other, from the implantation of the pellets of d.a.

It is clear from the results obtained that not only was there no deficiency of d.a. in Cases 2, 3, 4, and 5, but that they could be made worse (two cases) by a high salt intake or the parenteral administration of the hormone. The absence of reaction to the high chloride intake or hormone in the last two cases, as compared to Cases 2 and 3, might be explained by the fact that they were definitely milder. Conversely, the absence of reaction to implanted pellets in one severe case may be explained by loss of potency or by absorption too slow to cause ill effects.

It is not strange that d.a. failed to help, inasmuch as a study of its pharmacologic action leads one to expect negative results. Wells and Kendall<sup>3</sup> found that this hormone causes a drop in the concentration of K, an element essential in muscle function, in the blood serum of rats.

Loeb and his associates,<sup>4</sup> studying its action on dogs, observed "a peculiar weakness" when d.a. was given together with a high salt intake. Why, then, the apparent recovery in the first case? It may be that the patient was about to have a remission when the implantation was carried out. Such a coincidence is possible, but not probable, as the improvement was immediate and not gradual. Furthermore, an attempt made to discontinue prostigmin medication a few days before the operation resulted in full return of symptoms and at no time was she able to be up and about mornings unless she took her tablets one hour before arising. On the other hand, should we accept the beneficial effects

of the implantation, how can we explain the relief of symptoms long after the tablets should have been totally absorbed, seven months being the longest calculated period according to Soffer and his associates?<sup>5</sup> Yet this woman is better now, thirty-five months after the implantation, than she was at any time during the first half year.

Although so far the evidence is mostly against the usefulness of d.a. in myasthenia gravis, we cannot overlook Moehlig's case and the first one reported here. And the fact that the other cases did not respond to d.a. does not necessarily mean that there was no adrenal disorder. Other substances extracted from the adrenal cortex (cortico-terone or the cortin fraction<sup>6</sup>) will cause a reduction in the size of the thymus, an organ considered by some to be directly related to the cause of myasthenia gravis. The literature on this subject is reviewed by Blalock and his associates<sup>7</sup> in a paper describing the results of thymectomy.

### Case Reports

Case 1—V. H., age 35, a colored married woman, day, 1937. In 1937 she developed myasthenia gravis and she complained of diplopia. In August, muscular weakness began and rapidly became so severe that she was unable to walk without assistance and she developed a sense of great muscular fatigue on slight exertion. The patient had noticed for some time that there was a "drooping" of the eyelids at there

The neurologic examination showed marked weakness of all muscular groups with almost complete bilateral external ophthalmoplegia and ptosis. No sensory changes or disturbance of coordination were elicited. Routine laboratory tests were reported as negative.

An injection of prostigmin gave the patient definite though not very marked relief within a few minutes. She was discharged from the hospital with a diagnosis of myasthenia gravis. At different times she received vitamin B<sub>1</sub> and vitamin B<sub>12</sub>. The last was the most decided value and she eventually remained on that one drug alone. Up to November, 1940, she was kept fairly comfortable on 30 mg. twice daily by mouth. On several occasions she attempted to stop the medication but was unable to do without it.

On November 9, 1940, nine pellets of d.a. of 50 mg. each were implanted in the subcutaneous tissues of the abdomen. Two days after the operation the prostigmin was withdrawn and since that time the patient has been without it. The following notes were made nine days after the operation: "the patient has not taken prostigmin for the last seven days, yet shows no need for it, she can move the facial muscles well, walks with ease, and the eye movements are as good as when she was taking

prostigmin." Eleven days after the operation she was discharged from the hospital and since then she has been followed regularly at the clinic.

She was last seen August 6, 1943, thirty-five months after the implantation. Her strength continued to be good in all extremities as well as in the face, tongue, and throat. Movements of the eye muscles were slightly restricted in the upper gaze and there was partial left ptosis.

*Case 2.*—G. B., a 22-year-old woman, was admitted to the Neurological Institute on August 4, 1941, complaining of increasing weakness and fatigability. Sometime in 1935 the mother first noted that her speech was not clear and that at times her voice sounded like a horn. Soon there followed difficulty in swallowing and liquids would come out of the nose. Sometime later weakness in the legs, arms, and hands appeared, together with a dead expression in the eyes. She lost weight, going from 119 pounds to 105 pounds. Early in 1937 her breathing became affected, the eyes looked tired and watery, and finally she had to leave school. Examination revealed the typical findings of myasthenia gravis and the results of a therapeutic test with prostigmin were prompt, the patient improving markedly within a few minutes. For several months it was possible to keep her comfortable by administering 30 mg. of prostigmin with tincture of belladonna three times a day. Then her condition gradually became worse and the relief from prostigmin medication by mouth was less and less. In 1939 she was troubled with double vision and during the first six months of 1941 her dysphagia became more distressing, with increasing shortness of breath. Twelve hours before her admission her respiratory difficulty was so severe that it was necessary to administer oxygen. The past personal and the family history are noncontributory.

**General Examination:** The Blood pressure was 92/60. The patient was thin and pale and appeared to be chronically ill. Hypertrichosis was present in the lower extremities and the crines had male distribution. No pigmentation suggestive of Addison's disease was present. The left lobe of the thyroid was enlarged.

**Neurologic Examination:** Findings were typical, including severe general weakness, feeble and unintelligible speech, expressionless face, some limitation of the upward movements of the eyes, and bilateral ptosis. There was also some difficulty in swallowing and the tongue could not be protruded. Urine creatinine was 148 and the creatinine, 775. Other laboratory tests, including blood count, blood chemistry, and urinalysis, were negative.

**Course:** For a few days after admission the patient was given prostigmin by injection every four hours, with ephedrine by mouth three times a day. With this medication she improved considerably so that she was able to get up and around and eat fairly well. Once these results were obtained she was given the test for adrenal function, described by Cutler, Power, and Wilder.<sup>2</sup> The outcome of this test was a chloride concentration in the urine of 51.2 mg. per 100 cc. on the third day, therefore revealing adrenal function to be within normal limits. A few days later she was placed on a high sodium chloride intake, accomplished by intravenous injections of 20 Gm. of salt daily. No improvement followed; on the contrary, the patient was made weaker and it was necessary to increase the prostigmin dosage. After another period of rest, 5 mg. of d.a. were given by hypodermic injection on three successive days. The results were as bad as they

were with the high sodium diet and had to be discontinued. Not satisfied with the results and hopeful that there might be a difference in the mode of action between the hypodermic injections and the implanted pellets, I decided to carry out the latter procedure. On September 13, 1941, two 50 mg. pellets were implanted in the abdominal wall. Since no change at all was noted in her condition, on October 8, six fresh pellets were placed in the other side of the abdomen. She was finally discharged on December 3, eight weeks after the second implantation, having shown absolutely no effects, good or bad. An increase in the dose of prostigmin was not necessary, nor were we able to cut down on the medication.

*Case 3.*—L. B., a white girl, aged 11 years, was admitted to Fitkin Memorial Hospital, in Neptune, New Jersey, on August 17, 1942. She had first complained of general weakness about one year before. This weakness gradually increased, so that two months prior to admission she began to fall and have difficulty in going up and down stairs. She was less tired in the mornings and after resting she recuperated. About the same time her mother began to notice some drooping of the lids and weakness in her smile. She was less tired in the mornings and after resting she recuperated. When she was hurt in any way, her cry was weak. At about the same time she had difficulty in swallowing and her speech became thick. She has had double vision while in the movies and difficulty in keeping her eyes open. The neurologic examination revealed the definite findings of myasthenia gravis with expressionless face, thick speech, and drooping lids. Routine laboratory studies revealed nothing of significance. Basal metabolism was reported as minus 20; cholesterol, 140 mg. per cent. X-rays of the chest did not show an enlarged thymus. Chronaxie studies of the facial muscles revealed nothing abnormal, but after fatigue by faridization of the frontalis the chronaxie showed rapid exhaustion (Jolly reaction). Adrenal function was studied by means of the Cutler, Power, and Wilder test and was found to be normal—122 mg. of chlorides per 100 cc. of urine on the morning of the third day. One day of rest was allowed, after which, for a period of three days, she was put on a high salt diet by adding 20 mg. sodium chloride daily to the regular diet. On the third day this amount of salt had to be given by intravenous injection and was followed by a constitutional reaction which was considered to be due not to the chlorides but to the solution itself. After a short rest she was given 5 mg. of d.a. by hypodermic on two successive days and on the third day it was increased to 10 mg., without noticeable effect. On the morning of the fourth day the patient was again given 10 mg. and that afternoon there was a very severe reaction, with rapid breathing and thready pulse and inability to swallow or even to expectorate mucus. Following the injection of 1 mg. of prostigmin there was rapid improvement, with dropping of the respiration and pulse to normal. In order to substantiate the nature of this reaction she was allowed to go without any more prostigmin. About eight hours later she went into a similar state and again she recovered within a few minutes following prostigmin medication.

*Case 4.*—Mrs. L. T., a white woman, was first seen by me in February, 1941, when she was 21 years old. She gave a typical history of myasthenia gravis, with general weakness, initiated by drooping eyelids, which had started early in 1938. Eighteen months after the onset she was unable to bring

food to her mouth and there was difficulty in swallowing or chewing. There also developed diplopia and facial weakness and finally weakness of the lower limbs. The examination confirmed the impression obtained from the history and the response to prostigmin was definite. For the next two years she was kept active by the administration of prostigmin and ephedrine by mouth. On March 15, 1943, she was admitted to the Neurological Institute for studies. Routine laboratory tests were reported as negative; the basal metabolism was 0 and the x rays of the chest did not show enlargement of the thymus. The Jolly's reaction was positive in all the muscles tested.

She was given the Cutler, Power, and Wilder test for adrenal function and the urine on the morning of the third day was reported as containing 13.6 mg per 100 cc, a figure well within the normal. After a day's rest 20 Gm of sodium chloride daily were added to the regular hospital diet for three successive days. There was no unusual reaction. Again she was allowed to rest for one day and then was given 10 mg of d-a for two consecutive days. As no effect was noted, the same dose of d-a was given on the third day but all other medication was stopped. That afternoon she was observed to be unable to smile or swallow well and her general power was markedly diminished; it was necessary to give an injection of prostigmin.

Case 5—B. P., a 17-year-old white boy, was admitted to the Neurological Institute on April 28, 1943, with a history of double vision and drooping of the lids, beginning in the fall of 1940. The double vision had lasted only about two weeks, but since then he had found it necessary to turn the head when he wished to look to the side. These complaints were much less noticeable in the first half hour after arising in the morning. On examination, the only positive findings were bilateral ptosis and marked impairment of the extra-ocular movements. Injection of prostigmin hypodermically produced

considerable improvement within ten to fifteen minutes. Routine blood and urine tests were negative. Creatinine excretion was found to be 28 mg and creatinine 1,605 mg in twenty-four hours. X rays of the skull were reported to be normal.

As in the last three cases, the Cutler, Power, and Wilder test revealed normal adrenal function—50.5 mg per 100 cc of urine on the morning of the third day. A high sodium chloride intake (20 Gm daily) was then tried for three days without noticeable effect. After a short rest d-a was given hypodermically in 10 mg doses daily for three days and in 20 mg doses daily for three days more without causing any improvement or undue reaction.

### Summary

Five cases of myasthenia gravis are described, one of which was apparently improved greatly by implantation of d-a pellets. In this case no preliminary studies of adrenal function were made. The other four patients showed no deficiency of d-a secretion, one of them reacted poorly to a high salt intake, and two cases were aggravated by d-a given intramuscularly. The possibility that other fractions of the adrenal cortex may be involved is discussed.

A word of caution is in order: the implantation of d-a pellets in myasthenia gravis should be preceded by studies of adrenal function and trial injections.

### CADET NURSES CELEBRATE BIRTHDAY

July 1 has been designated the official birthday of the U S Cadet Nurse Corps. Dr Thomas Parran, Surgeon General of the U S Public Health Service, Federal Security Agency, has announced. The first anniversary was celebrated this year.

Youngest and largest of the women's uniformed organizations in the country, the corps now boasts a membership of nearly 100,000 young women, all pledged to remain in essential nursing—either civilian or military—for the duration of the war.

These recruits, identified by their Montgomery berets and their trim gray uniforms marked by silver Maltese crosses and red epaulets, are helping to make it possible for hospitals to release graduate nurses for specialized positions on the home front and behind the fighting lines.

In 1,065 schools of nursing across the country these young women, from all walks of life, are already contributing greatly to the wartime nursing program as they prepare to be nurses. Dr Parran said. They come directly from high school graduations, from colleges, from business offices, and are wives and sisters of fighting men, daughters of war

workers, farmers, and professional men, Dr Parran added.

Special tribute to the schools of nursing where d was paid by

1. - public spirited  
allantly to  
go much of  
during the  
first year of the U S Cadet Nurse Corps," Dr Parran said.

Because of the heavy study and work schedules in hospital schools, only simple ceremonies were planned for the corps' first birthday. Special events were held in New York, Chicago, Hollywood, Fort Worth, and several other cities. For the most part, celebrations were limited to teas, dinners, or other parties arranged by the individual schools of nursing. A birthday cake decorated with the emblem of the corps was the center of interest at many affairs. Sharing in some of the observances were prominent State and community officials—

## TREATMENT OF PSEUDO-EPILEPSY

F. D. BROWN, M.D.,\* Hobart, New York

THE symptoms and treatment of two patients afflicted with pseudo-epilepsy are given in the following report. This demonstrates the possibilities that are open to the physician who will individualize his study of these interesting and all-too-often neglected cases. Since the cause and cure of a case presenting pseudo-epileptic symptoms have not as yet been proved, any safe method of therapy is most welcome to the harassed patient.

True idiopathic epilepsy can be ruled out by the classical history, a clinical test, and the encephalograph. It is also generally recognized that hypothyroidism, calcification of the adrenals, cerebral cortical lesions, and adenoma of the pancreas may bring on epileptiform or pseudo-epileptiform attacks.

Cases not in the above categories, however, present a problem the successful solution of which requires sympathetic understanding by the physician in each individual case and careful treatment usually over a long period of time.

### Report of Cases

*Case 1.*—The patient was a clerk aged 25. Following an attack of scarlet fever at the age of 15, he was afflicted with so-called epileptic attacks. For six months he received gradually increasing doses of phenobarbital but this treatment failed to prevent the frequency and severity of the seizures, which were occurring almost once a week and which fitted a textbook description of an epileptic attack with the exception of the history of onset after scarlet fever. The rest of the history was negative, as were both the mental and the physical examinations.

Since the patient was not improving under phenobarbital and dilantin sodium combinations, it was decided to give him an ampule of scarlet fever antitoxin. Because he had never had any symptoms prior to his severe attack of scarlet fever, it was felt that he did not have true idiopathic epilepsy. Hence, after a negative ophthalmic and intradermal test, the antitoxin was injected into the gluteal muscle. Five days after the injection, the patient developed a

severe serum reaction with a rectal temperature of 104 F., pulse 120 per minute, a polyarthritis, and a generalized urticaria. No medication was given to modify the reaction. This subsided gradually over a period of five days. At this time, one kapsel of dilantin sodium after breakfast and phenobarbital,  $\frac{1}{2}$  grain at bedtime, were started. At the end of two months these were discontinued. In the following two years, he had only one attack. This occurred three months after the antitoxin injection when he had overworked for about a week.

*Case 2.*—A housewife, aged 48, complained of epileptic attacks since childhood. Antispasmodic treatment during the preceding year had not been successful unless she took large doses of phenobarbital. The attacks would occur once or twice a month and consisted of falling and then a tonic convulsion which soon changed to the clonic type. The attacks never lasted more than three to five minutes. Control of the anal and vesicle sphincters was not lost.

At 23 years of age she had a normal pregnancy and delivery. During her pregnancy and for two years thereafter she suffered no attacks. The rest of the history and examinations were negative. Despite the history of the early onset of her attacks, it was not felt that she had true epilepsy because of the nature of the episodes. Since she had not been afflicted during her pregnancy and for two years thereafter, it was decided to try antuitrin-S. Accordingly, 3 cc. were given every other day for two weeks, then 2 cc. every third day for two weeks, until at the end of two months she was giving herself 1 cc. per week. Treatment did not effect normal menstrual periods. At the time of writing this patient has been free from symptoms for one and one-half years.

### Conclusions

1. The possibility of attacks with definite cause and responding to specific therapy should be eliminated.
2. Patients having pseudo-epilepsy may still be benefited without a life sentence to antispasmodics.
3. It is hoped that this brief report may stimulate physicians to further individualized clinical study of pseudo-epilepsy.

\* Since writing this paper Dr. Brown has joined the armed services as a captain in the Medical Corps of the United States Army.

### REFRESHER COURSE IN OTOLARYNGOLOGY IN CHICAGO

The University of Illinois College of Medicine announces that its fall didactic and clinical refresher course for specialists in otolaryngology will be held at the College from September 25 to 30, inclusive.

Since registration is limited to twenty-five, applications should be filed as early as possible. Write for information to Department of Otolaryngology, University of Illinois College of Medicine, 1853 West Polk Street, Chicago 12, Illinois.

# Case Report

## ACUTE INFECTIOUS MONONUCLEOSIS WITH HEPATITIS

### Presentation of Two Cases

MILTON H. MORRIS, M.D., ABNER ROBBINS, M.D., AND EDWARD RICHTER, M.D.,  
Far Rockaway, New York

THE protean manifestations of infectious mononucleosis have at times puzzled the internist. The delayed and variable hematologic findings, together with the inconsistency of the Paul-Bunnell heterophile reaction, only add to the confusion of the clinical picture in the early stages of the disease. The original description of Pfeiffer emphasizes the diagnostic triad of glandular fever as glandular enlargement, high temperature, and mononucleosis.

Drs. J. Shafar and J. C. Weir<sup>1</sup> describe infectious mononucleosis with a clinical picture dominated by meningeal symptoms. Other cases of the disease in which abdominal or cerebral manifestations have been prominent are presented in the literature. An asymptomatic or abortive type is also mentioned as a distinct clinical picture. It is the opinion of Shafar and Weir that there may be separate and distinct clinical varieties of the disease.

The association of infectious mononucleosis with jaundice was first mentioned by Downey and McKinley<sup>2</sup> in 1923, emphasized by de Vries in 1938, and more recently brought forward by Martin, Carter, and Gold<sup>3</sup> in 1941 and 1942.

McKinley<sup>4</sup> in 1935 reported jaundice five times in 50 cases, but Bernstein's<sup>5</sup> group of 65 cases included only one with this finding. Excepting Martin's<sup>6</sup> figure of 13 previously reported cases, including the recent additions, there are, up to date, reported in the literature 21 cases of infectious mononucleosis with jaundice.

The cause of the jaundice is assumed by the above authors to be associated with biliary obstruction, as a result of the pressure of the enlarged lymphatic glands in the hilum of the liver. These cases were at some time during the course of the disease associated with glandular adenopathy and most often the appearance of the jaundice coincided with the generalized adenopathy.

DeVries<sup>7</sup> recognized three types of jaundice in glandular fever: (a) "forme ictérique à début ganglionnaire", in which the glandular enlargement was prominent and jaundice developed during the course of the disease; (b) a "forme à début ictérique", in which the jaundice was the first symptom and glandular enlargement followed; and (c) very rare cases in which jaundice and pyrexia were the only symptoms and the diagnosis rested on the hemato-

logic findings and the Paul-Bunnell heterophile reaction.

DeVries reports two cases representative of types (a) and (b) and explains that jaundice found in the above-mentioned cases is the result of portal obstruction.

We wish to report two cases of acute infectious mononucleosis with jaundice which fall into group (c), in that they were associated with pyrexia and the absence of glandular enlargement and in which confirmatory laboratory studies revealed the jaundice to be the result of a true hepatitis.

### Case Reports (See Table 1)

**Case 1.**—H. P., a man aged 23, was admitted to St. Joseph's Hospital, Far Rockaway, New York, on November 17, 1943. His chief complaints were chills, fever, and severe pain in the right upper quadrant of the abdomen.

**Physical Examination:** Physical examination showed him to be a well-nourished white man appearing acutely ill. There was an icteroid discoloration of the conjunctivae. A fine yellowish discoloration of the skin was also present. There were no evidences of glandular enlargement. The spleen was not enlarged. The abdomen was slightly distended and there was tenderness in the upper right abdominal quadrant. The liver was palpably 2 cm. below the right costal margin. The physical examination was otherwise normal.

**Laboratory Reports:** A flat x-ray plate of the abdomen showed all soft tissue detail to be obscured by intestinal gas. No calcified or other shadows were disclosed.

Other laboratory findings were: On October 18, 1943, phosphorus was 2.9 mg. per 100 cc.; phosphatase, 18.2 units; nonprotein nitrogen, 40 mg. per 100 cc.; icterus index, 30 units. The van den Bergh reaction was immediate, direct, and weak. The urinalysis showed no leucine or tyrosine crystals.

The bleeding time was three minutes, the clotting time three and a half minutes; the prothrombin time was thirteen seconds; the platelet count was 180,000, and the fragility test showed that hemolysis began at 0.4 and was complete at 0.3 per cent saline.

The Widal O and H typhoid test and the paratyphoid A and B test were negative. The brucella agglutination test and the Proteus OX10 test were negative. Hydrobilirubin was present in the stool; the stool culture was negative for enteric organisms. The blood count: hemoglobin, 108.4 per cent, red blood cells, 5,150,000, white blood cells, 11,700; polymorphonuclears, 25

Director of the Department of Medicine, St. Joseph's Hospital, Far Rockaway.

Associate in Medicine, St. Joseph's Hospital, Far Rockaway.

Associate in Medicine, St. Joseph's Hospital, Far Rockaway.

per cent; lymphocytes, 33 per cent; monocytes,\* 42 per cent.

The urine was a dark orange color; specific gravity was 1.015. A trace of albumin was present; there was no sugar or acetone. A number of bacteria were found. A few white blood cells and bile were present. The tests for urobilin and urobilinogen were strongly positive.

On October 19 Weil's test showed no agglutination in dilutions of 1:10 to 1:1280. On October 21 the blood count was: white blood cells, 16,500; polymorphonuclears, 22 per cent; lymphocytes, 16 per cent; monocytes and immature cells, 62 per cent. On October 22 the blood count was: white blood cells, 16,500; polymorphonuclears, 26 per cent; lymphocytes, 39 per cent; immature cells identified as monocytes, 35 per cent. The Kline test was negative.

On October 23, 1943, the cephalin flocculation test was 3 plus. The icterus index was 28 units. On October 26 the urine showed a yellow color; acid reaction; specific gravity of 1.003; no albumin; no sugar; no acetone; urobilinogen strongly positive.

On October 27 the icterus index was 17 units; the van den Bergh test gave no reaction; the stool culture was negative for ova and parasites. The blood count: white blood cells, 12,000; polymorphonuclears, 22 per cent; lymphocytes, 30 per cent; eosinophils, 1 per cent; atypical mononuclear cells, 47 per cent.

On October 29 the cephalin flocculation test was 3 plus. Heterophile reaction: sheep cells agglutinated up to serum dilution of 1:64.

Clinical Course: The temperature varied from 100–101 F. down to normal during the patient's stay of about two weeks at the hospital. The pulse fluctuated between 70 and 80 to the minute. The respirations were normal. The abdominal pain gradually subsided. The liver edge was still palpable at the time of discharge and there was still an icteroid tinge to the sclerae. The blood picture still showed neutropenia with monocytosis. Clinically the patient was well.

Case 2.—S. N., a physician aged 37, was admitted to St. Joseph's Hospital, Far Rockaway, New York, on November 12, 1943. His chief complaints were severe pain in the small of the back, chills, and high temperature.

Relevant History: The patient had been ill for four days prior to admission into the hospital and had taken 105 grains of sulfamerazine without any apparent effect.

Physical Examination: Physical examination revealed an obese white man, apparently acutely ill. The abdomen was obese and palpation of liver and spleen was difficult. No glandular adenopathy was found, except for an icteroid tinge to the conjunctivae.

Laboratory Reports: Portable x-ray of the chest showed a thin haziness at the left base, suggesting an early pleural reaction of a minimal degree. There was no evidence of fluids in the chest. There were no areas of pneumonitis.

On November 12, 1943, the typhoid O and H, paratyphoid A and B, brucella and Proteus OX19, tests showed no agglutination. The icterus index was 30 units. On November 13, 1943, the heterophile reaction showed sheep cells agglutinated up to serum dilutions 1:4. The Widal test was neg-

\* Many of the monocytes were atypical, some resembling intermediate cells, others immature monocytes and lymphocytes. Repeat smear requested.

TABLE 1

	Case 1	Case 2
Phosphorus	2.9 mg./100 cc.	Test not done
Phosphatase	18.2 units	Test not done
Nonprotein nitrogen	40 mg./100 cc.	25 mg./100 cc.
Icterus index	30 units	37.5 units
Urine crystals	No leucine or tyrosine	No leucine or tyrosine
Bleeding time	3 minutes	3 minutes
Clotting time	3½ minutes	5 minutes
Prothrombin time	13 seconds	15 seconds
Platelet count	180,000	200,000
Fragility	Hemolysis begins at 0.4 per cent and is completed at 0.3 per cent	Hemolysis begins at 0.42 per cent and is completed at 0.32 per cent
Widal	Negative	Negative
Paratyphoid A & B	Negative	Negative
Brucella	Negative	Negative
Proteus OX19	Negative	Negative
Kline	Negative	Negative
Stool hydrobilirubin	Positive	Positive
Stool culture	Negative for enteric organisms	Negative for enteric organisms
Cephalin flocculation	3 plus	3 plus
Heterophile	Sheep cells agglutinated up to serum dilution 1:64	Sheep cells agglutinated up to serum dilution 1:32
Weil's disease	Negative	Negative
van den Bergh	Weak, immediate, direct	Delayed, direct, weak
Parasites	Ova and parasites —negative	Ova and parasites negative — Salmonella (non-pathogenic)

ative. The stool culture showed Salmonella (non-pathogenic). Hemolysis began at 0.42 per cent saline and was complete at 0.32 per cent. Bile was present in the urine, which was brownish in color. The reaction was acid, and the specific gravity was 1.030. No albumin, sugar, or acetone was present. Microscopic examination revealed many mucous threads, squamous epithelium, calcium oxalate crystals, and occasional red and white blood cells.

The blood count: hemoglobin, 90.9 per cent; red blood cells, 5,140,000; white blood cells, 5,050; polymorphonuclears, 40 per cent; lymphocytes, 43 per cent; monocytes, 15 per cent; juveniles, 2 per cent. The blood smear was negative for malaria; the prothrombin time was 15 seconds.

On November 15 the icterus index was 37.5 units; the van den Bergh reaction was delayed, direct, and weak. The urine culture was negative for typhoid and brucella. The blood count: white blood cells, 7,100; polymorphonuclears, 47 per cent; lymphocytes, 43 per cent; monocytes, 8 per cent; juveniles, 2 per cent; many endothelial cells were noted.

On November 17 the blood culture showed no growth in five days. No enteric organisms were found in the stool culture. Slight hemolysis was present, according to the icterus index.

The cephalin flocculation test was 3 plus, and the van den Bergh test gave no direct reaction. The blood count: hemoglobin, 89.3 per cent; red blood cells, 4,850,000; polymorphonuclears, 13 per cent; lymphocytes, 64 per cent; monocytes, 23 per cent.

On November 23 the icterus index was 15 units. The typhoid O and H, paratyphoid A and B, brucella, and Proteus OX19 tests all showed no agglutination. The stool culture was negative for enteric organisms. The heterophile reaction showed sheep cells strongly agglutinated up to serum dilutions of 1:32.

Clinical Course: The patient remained at the hospital for seventeen days. For the first three

days his temperature ranged in the neighborhood of 104 F. and then dropped, assuming a low-grade character until just before his discharge. The pulse varied between 70 and 90. The respirations were normal. After the seventh day the patient improved clinically.

At the time of his discharge the icterus had disappeared and the only complaint was that of fatigue and weakness.

### Discussion

The two cases described present certain features in common—viz.: jaundice, an unusual blood picture with neutropenia and monocytosis, a delayed Paul-Bunnell heterophile reaction, a variable van den Bergh reaction, one case showing an immediate direct reaction and the other a delayed direct reaction, but both reactions were weak and became negative in a short time, and an absence of glandular adenopathy. Case 1 presented the additional feature of an enlarged and tender liver. In Case 2, because of the obesity of the patient, it was impossible to palpate any of the abdominal organs.

The laboratory data were very similar and were indicative of parenchymal liver damage. The absence of hemolysis and an increased urobilinogen associated with a strongly positive cephalin flocculation reaction is confirmatory of liver damage. The fall in the plasma prothrombin is also a sign of early hepatic dysfunction. Kaplan, Stewart, and Lyons<sup>8</sup> demonstrated this early fall in their

studies of hepatic disturbances as a result of sulfonamide therapy.

### Conclusion

1. Infectious mononucleosis may present a bizarre clinical picture and often requires considerable laboratory study, as was the necessity in the afore-mentioned cases.

2. The association with jaundice is a rare occurrence and serves further to obscure the clinical picture.

3. The cases of infectious mononucleosis described in the literature explain the jaundice as a result of pressure of enlarged glands in the hilum of the liver, the so-called regurgitant type.

4. We have presented two cases of infectious mononucleosis with jaundice in which the jaundice was dependent on actual parenchymal liver damage.

5. Infectious mononucleosis with hepatitis is a definite clinical picture and may occur without the presence of adenopathy and may require considerable laboratory study for its interpretation.

### STUNG BY VITAMIN BILE

Don't look now, but you are in the midst of the greatest vitamin boom of all time. There was a period when we considered a vitamin as a small atomic organic substance found only in minute amounts in food, now what have we?

Vitamins can be bought by the barrel and are in every drug and department store and in some grocery stores. Vitamins are being added to various foods to make them more attractive and nutritious.

It is even rumored that vitamin B will soon be added to gasoline if they can find some reason for it. The height of chicanery was reached a short time ago when a local drugstore opened a "Vitamin Bar," the inference being that one may get a snootful of gelatin highballs and have a round of fun without the usual 4 m. residual.

The newspapers, magazines, and radios are all playing their part in distributing misleading facts about the virtues of certain vitamin products. The following are some of the more common ones:

"Vitamin B is the most important vitamin for the human body. It is found in almost all foods. It is essential for the normal growth and development of the body. It is also essential for the normal functioning of the nervous system. It is therefore, a very important vitamin for the human body."

and have received the seal of approval of Light

Housekeeping magazine. Remember, s-t-u-n, spelled backwards, is n-u-t-s." (You can say that again.)

The medical profession has allowed the vitamin situation to get out of bounds so that very little scientific control of administration is exercised. Many times it comes under the head of nonspecific therapy. The indiscriminate use of vitamins may have been enhanced by a recent diagnostic innovation called "subclinical deficiency states." After all, there is considerable glutin in these products, which in itself is an excellent protein substitute, lacking but two important amino acids, tryptophane and lysine.

It is also true that there are specific vitamin deficiencies, but symptoms such as loss of appetite, nervousness, headache, malaise, fatigue, irritability, and loss of weight are very often on the basis of something more serious than a vitamin deficiency.

Are we allowing our professional approval to be used for a nonspecific therapeutic element to build up big fortunes for pharmaceutical houses, or is there an actual need for this maelstrom of synthetic, gelatin superchargers now glutting the market?—J. Lightbody, M.D., in *Detroit Medical News*

# Postgraduate Medical Education

*Programs arranged by the Council Committee on Public Health and Education of the Medical Society of the State of New York are published in this section of the JOURNAL. The members of the committee are Oliver W. H. Mitchell, M.D., Chairman (428 Greenwood Place, Syracuse), George Baehr, M.D., and Charles D. Post, M.D.*

## "Penicillin Therapy" at Clinton County

POSTGRADUATE instruction on penicillin therapy has been arranged for a meeting of the Clinton County Medical Society to be held Monday, July 3, at 6:30 P.M. in the Hotel Witherill, Plattsburg.

A dinner will precede the meeting.

Dr. L. Whittington Gorham, professor of medi-

cine, Albany Medical College, Albany, will be the lecturer.

This instruction is presented as a cooperative endeavor of the Council Committee on Public Health and Education of the Medical Society of the State of New York and the New York State Department of Health.

## Lecture on Orthopaedics at Massena

THE St. Lawrence County Medical Society met on July 13 at 1:00 P.M. in the Massena Country Club, in Massena, for postgraduate instruction. Dr. Roscoe D. Severance, associate professor of orthopaedic surgery at Syracuse University College

of Medicine, in Syracuse, delivered a lecture entitled "Common Orthopaedic Defects."

It functioned as a . . . New York health

## OPEN SESAME!

The first steps in the making of a doctor are college and medical school education, along with internships. These will not be discussed here. Their cases are quite debatable as to time spent and subjects studied.

It is more interesting to delve into the ways and means of continuously educating oneself. It is amazing and deplorable to see how often medical

... a longer period of training before giving a novice the privilege of practicing, but since Medicine must

Yes—but in part only. Is it by attending clubs, county medical meetings, state or national meetings? Yes—in part only, again. Certainly these are necessary and play a vital part in the continuous process of education. They must never be discontinued.

Naudé has said, "Learning, as with water, is never more fair, pure, and simple than at its source." One of the definitions of Open Sesame is, "a magical key—something that unfailingly opens or admits." Now what can this be? Of course, it is Dr. William Osler's Master Word—"Work." One must study at the source (in postgraduate schools) and be instructed at regular periods, else he runs into a rut, into careless habits and loose thinking. A good athlete, for example, knows he must be instructed often to improve his game. However, some medical men feel that they are being belittled if it is sug-

gested to them that they should become students again. Patients are cognizant of the fact that medicine is advancing by leaps and bounds, and they must demand that their doctors keep abreast of the times. It is necessary that we should be students to the end. This is true of both practitioners and instructors.

It is highly desirable to go forward to postgraduate schooling, to study the progress in the medical arts. Here one sees new experiments and the way the experimenter works. Here one examines new data and is trained in their application. It is most stimulating for one to attend, yearly, some planned advanced course of instruction. If yearly courses are not practical in a given case, then biennial ones can be chosen. In this way one will be searching for the truth and keeping up with it. Dr. William Mayo phrased it thus: "Truth is a constant variable, add a fact and change the outlook, and you have a new truth." In other words, truth is constantly changing—and one must change with change.

which can be carried out by anyone who aspires to attain advanced knowledge of the best in the medical arts. Your practice will not suffer—nor contra-

arts will be required every few years. All would then see the need for the program of continuous education.

It is in this way that we will forge ahead from present imperfect to future perfect—*Max Wolfson, M.D., in California and Western Medicine*

# Medical News

## Recruitment of Physicians for Army, Navy, and Veterans Administration

**R**ECRUITMENT procedures under which the state chairmen for physicians have operated for some time will be changed as a result of the following developments in the needs of the Army, Navy, and Veterans Administration:

1. *Relaxation of Age and Other Requirements of the U.S. Navy.*—The U.S. Navy Medical Corps recently has increased its age limit to 55 years. Physical requirements also have been relaxed, with the result that men who have expressed a preference for Army service may be referred to the U.S. Navy for consideration for commissioning by the Navy.

2. *Requirements of the U.S. Army.*—The U.S. Army Medical Corps will continue to commission for general and limited service men up to the age of 45 who have been declared available by the Procurement and Assignment Service. In exceptional cases the U.S. Army will continue to waive age requirements for men for specific position vacancies.

3. *Requirements of the Veterans Administration.*—Since December, 1943, the need of the Veterans Administration for qualified physicians has greatly increased. Therefore the following plans have been set up:

(a) Physicians under 45 years of age made available to the Army and who are not physically

qualified for duty with Army installations but who meet Veterans Administration requirements will be given Army commissions for assignment to duty with the Veterans Administration.

(b) Physicians under 55 years of age made available to the Navy and who are not physically qualified for duty with Navy installations but who meet Veterans Administration requirements will be given Navy commissions for assignment to duty with the Veterans Administration.

(c) Physicians between the ages of 45 and 63 years who have been declared available for appointment by the Army will be offered commissions by the Army for assignment to duty with the Veterans Administration only, except that those between the ages of 45 and 55 years found physically qualified for general service will be submitted by the Army to the Navy for consideration for duty with the Navy.

(d) Since the Navy will not appoint any physician who has passed his sixtieth birthday for duty with Navy installations or the Veterans Administration, all available physicians between the ages of 60 and 63 should be made available to the Army only for duty with the Veterans Administration.—*J.A.M.A., May 27, 1944*

## Civilian Specialists Appointed to Office of Surgeon General

**N**INETEEN civilian consultants were recently appointed to the Office of the Surgeon General as advisers to the Army Medical Department on problems of internal medicine.

The appointees for the respective specialties are: gastroenterology, Dr. Walter L. Palmer, University of Chicago, and Dr. Chester M. Jones, Harvard University; heart disease, Dr. Paul D. White, Massachusetts General Hospital, Boston, and Dr. Robert L. Levy, Columbia University; skin diseases, Dr. Joseph G. Hopkins, Columbia University, and Dr. John H. Stokes, director, Institute for Control of Syphilis, University of Pennsylvania; infectious diseases, Dr. Colin M. MacLeod, New York University, Dr. W. Barry Wood, Jr., Washington Univer-

sity, St. Louis, Dr. Charles E. Smith, Stanford University, and Dr. Caroline B. Thomas, Johns Hopkins University; chemotherapy, Dr. Chester S. Keefer, Boston University; allergy, Dr. Robert A. Cooke, Cornell University, and Dr. Francis M. Rackemann, Massachusetts General Hospital, Boston; tropical diseases, Dr. Robert B. Watson, principal malarialogist, Tennessee Valley Authority, Dr. James A. Shannon, New York University, Dr. Harold W. Brown, Columbia University, and Dr. Mark F. Boyd, director of the Station for Malaria Research, Tallahassee, Florida; tuberculosis, Dr. James J. Waring, University of Colorado, and Dr. James. Burns Amberson, Jr., Columbia University.—*J.A.M.A., June 24, 1944*

## Dr. Woolley Heads American Medical Women

**D**R. ALICE STONE WOOLLEY, of Poughkeepsie, is the new president of the American Medical Women's Association, having been elected at the recent annual meeting of the association held in Chicago. Dr. Woolley had served as president-elect of the association since its annual meeting of 1943.

Dr. Kate Savage Zerkoss, of Tennessee, succeeded Dr. Woolley as president-elect of the association.

Dr. Woolley is the third woman of the Poughkeepsie area to have been elected president of the American Medical Women's Association. Former presidents of the national organization, which was established in 1915, included the late Dr. Grace N. Kimball, of Poughkeepsie, and the late Dr. Elizabeth B. Thelberg, who was professor of physiology and hygiene, and physician, at Vassar College during the years 1887-1930. Dr. Kimball held the medical

association position during 1922-1923, and Dr. Thelberg in 1927-1928.

A fellow of the American Medical Association, Dr. Woolley is a past-president of the Women's Medical Society of New York State, and has been active on behalf of State and Federal government legislation in the interest of her profession.

During the last war, Dr. Woolley was awarded the Medaille de la Reconnaissance Française by the French government in recognition of two years of military service overseas.

Engaged in general practice in Poughkeepsie now, Dr. Woolley is a member of the courtesy staffs of St. Francis' and Vassar hospitals and the Northern Dutchess Health Center at Rhinebeck. She is a member of the boards of Bowne Memorial and Samuel and Nettie Bowne hospitals, and is vice-president of the former institution.

Dr. Woolley is a director of the Dutchess County

the  
the  
ster,  
American Red Cross A former director of physical  
education at the local Y.W.C.A., she had long been  
actively interested in the work of that association

She is a native of Yankton, South Dakota She

Trudeau Medal Awarded to Dr. James Alexander Miller

A HIGHLIGHT of the fortieth annual meeting of  
the  
Chicago, .  
Medal to  
the Board  
tion  
The citation given to Dr. Miller reads in part  
"a distinguished clinician who has given much of his  
life's work in a successful struggle against tubercu-  
losis in the nation's largest city, New York. There,  
having participated in instigating measures com-  
bating tuberculosis, he has had the inestimable joy

of living to see the tuberculosis death rate of 280  
per hundred thousand residents decline to that of  
48"  
Dr. Miller, the first president of the New York  
Tuberculosis Association after its separate incor-  
poration in 1919, has been a guiding influence in its  
work and that of its predecessor, the Committee on  
Prevention of Tuberculosis of the Charity Organiza-  
tion Society, since 1905. He is professor of clinical  
medicine at the College of Physicians and Surgeons,  
Columbia University—*Journal, N. Y. Tuberc. and  
Health Assn*

Officers of State Association of School Physicians

A T HIS recent annual meeting, the New York  
State Association of School Physicians elected  
Dr. Clarence A. Greenleaf, of Olean, to the office of  
president. Dr. Edgar Bieber, of Dunkirk, was re-  
elected vice-president, and Dr. C. Adela Brown,  
of Oswego, secretary-treasurer

Dr. John E. Burke, of Schenectady, former presi-  
dent of the organization, became a member of the  
Executive Committee in place of Dr. Greenleaf  
committee are Drs  
Lewis Wade Heizer,  
vitan, of Rome

County News

Albany County  
Dr. Harold W. Brown, authority on tropical dis-  
eases, discussed their diagnosis and treatment before  
the Albany County Medical Society on May 17  
Dr. Brown is professor of parasitology, at the  
College of Physicians and Surgeons, Columbia Uni-  
versity, New York City. Most of his discussion  
was devoted to malaria and filariasis \*

His first-hand study of tropical diseases in Mexico  
and Guatemala has convinced Dr. Perkins that  
diagnostic and treatment problems, rather than  
the danger of spread of new diseases in New York  
State, will accompany the return of troops from  
tropical theaters of war \*

Dr. James E.  
Communicable I  
Health, has ret  
clinical study spc—  
tion  
Although New York State does not have the neces-  
sary climatic and other factors for spread of tropical  
disease, Dr. Perkins said "a slight increase in  
malaria" might be expected with the returning  
troops

At the meeting of the county society on June 28  
Dr. Joseph S. Lawrence, Executive Officer of the  
Medical Society of the State of New York, spoke  
on the Wagner-Murray-Dingell bill. General dis-  
cussion followed Dr. Lawrence's address.

Nine doctors who are graduates of Albany Medical  
College, class of 1899, held a reunion banquet in  
Albany on May 13  
They were: Drs. George E. Beilby, of Albany,  
Walter A. Leonard, of Cambridge; Karl A. Parshall,

\* Asterisk indicates that item is from a local newspaper

of Brooklyn; George W. Ross, of Port Ewen; Walter H. Sanford, of New York City; W. A. Wardner, of Saranac Lake; and H. J. White, William Kirk, Jr., and J. H. Flynn, of Troy.\*

Effectiveness of the revised Workmen's Compensation Law rests with the medical profession, Dr. Herbert H. Baucus, New York State Medical Society president, declared in an address at the first annual conference of the industrial nurses' section of the New York State Nurse Association in Albany on June 19. The new legislation places regulation, inspection, and investigation phases largely in the hands of local medical societies, he said.

"In communities of less than one million persons, the county medical society has an official status under the law. While the changes are meant for the good of the patient, they will require the co-operation of the medical profession."

He said that the cost of compensation, if paid directly by the employer, actually is a charge against the consuming public. "Inferior medical care prolongs the disability and thus increases this cost."

"It is the desire of the medical profession to reduce the length of disability, to decrease the cost of compensation, while still providing proper care to the injured worker, and thus correct former evils."\*

#### Cattaraugus County

At the June 22 meeting of the county society the following officers were elected: Dr. M. G. Sheldon, of Olean, president; Dr. L. R. Stoll, of Salamanca, vice-president; and Dr. Wendell R. Ames, of Olean, secretary-treasurer.

#### Chemung County

Dr. Ethan Flagg Butler, lung specialist who left Elmira early in 1936, has returned to that city to resume practice.

Dr. Butler left Elmira to become thoracic surgeon to the New York State Tuberculosis Hospitals and was stationed at Biggs Memorial Hospital near Ithaca. Last September 1 he resigned from this position and moved to Syracuse, where he has since been a member of the staff of the Onondaga Sanatorium.\*

#### Chenango County

Fourteen physicians were present for the dinner and meeting of the Chenango County Medical Society held June 13 at the Blue Stone Golf Club. A delicious steak dinner was served the members.

Dr. E. F. Gibson, president of the society, presided. Dr. A. H. Evans, of Guilford, read a paper tracing the history of the county society from its formation in 1806 to the present time. There was also a general discussion of medical topics and the society went on record as opposed to socialized medicine and government control of doctors.\*

#### Clinton County

On May 16, at the Hotel Cumberland, in Plattsburgh, was held the regular semiannual meeting of the Medical Society of the County of Clinton.

The towns of the county were well represented by the physicians present. The meeting was presided over by Dr. Phillip B. Barton. Several matters of interest were discussed and the report of the delegate to the recent meeting of the State Society was given by Dr. Leo F. Schiff.

Miss Emily Creevey, representing the New York

State Nursing Council for War Service, spoke on the importance of maintaining local nurse civilian situations, which are essential, and at the same time furnishing a sufficient quota to the Procurement and Assignment Service for military purposes.

After dinner the members were given a treat by two officers of the Navy who are now stationed at Camp Macdonough in Plattsburgh. R. J. Williams, Commander, USNR, spoke on the "Duties of a Naval Medical Officer Afloat." R. H. Kiene, Lieutenant Commander, USNR, spoke on "Duties of a Naval Medical Officer Assigned to the Marine Corps."

Both of these officers spoke in a very entertaining way of the varied experiences they had had while on active duty and the difficulties encountered under battle conditions in furnishing prompt and efficient attendance on the wounded.

Capt. T. M. Downs, M.C., USNR, who was expected to speak, was recently transferred from Camp Macdonough.

#### Columbia County

The county society held its semiannual meeting on May 9 at the Columbia Golf and Country Club, with Dr. Cecil Schultz presiding.

Plans were discussed for the formation, under the auspices of the society, of a lay organization for the dissemination of knowledge for the control and cure of cancer. The organization is not yet complete, but will be in the near future. Dr. Caldwell B. Esselstyn is chairman of the committee.

Members of the society witnessed a moving picture, with sound, illustrating the diagnosis and treatment of syphilis. The film, put out by the U.S. Public Health Service, was shown by a representative of the New York State Department of Health.\*

#### Dutchess County

The county society held its May meeting at the Northern Dutchess Health Center on May 3 at 8:30 P.M. The scientific paper was given by Dr. J. Lewis Amster, honorary consulting surgeon at the Morrisania City Hospital, New York. The paper, "Advances in Local and Regional Anesthesia," was supplemented with a motion picture demonstration. Dr. Paul M. Wood, attending physician in anesthesiology, Lincoln Hospital, New York City, opened the discussion.\*

The regular meeting and annual outing of the county society was held June 14 at the Harlem Valley State Hospital, Wingdale.

Colonel Lasher, of the U.S. Military Academy at West Point, was the speaker.\*

#### Erie County

A talk on "Treatment of Acute Hand Infections and Treatment of Burns" was given by Dr. Henry H. Ritter, professor of clinical surgery, New York Post-Graduate Medical School of Columbia University, at a meeting of the Erie County Medical Society on May 24. A question-and-answer period followed the presentation.\*

Dr. Herbert H. Baucus, of Buffalo, President of the Medical Society of the State of New York, was one of the speakers at the Annual Conference of

Health Officers and Public Health Nurses, which was held in Saratoga Springs June 27-28

#### Fulton County

Dr Meyer A Rabinowitz, physician-in-chief at the Brooklyn Jewish Hospital, was guest speaker at a dinner meeting of the county society on May 24 at Nixon's Hotel at Pine Lake. Dr Morris Kennedy, president, presided at the session.

About twenty-five members attended the meet-

gained from years of study and travel in Europe \*

#### Herkimer County

Dr. Leon H. Griggs, dermatologist, of Syracuse, presented an illustrated lecture on common and industrial dermatoses at the regular June meeting of the county society on June 14 at the Mohawk Valley Country Club. A dinner followed the meeting \*

#### Jefferson County

The members of the Jefferson County Medical Society held their annual outing and dinner at the Frontenac Springs Hotel on June 8. The arrangements were in charge of Dr Edwin W. Roberts. There were about 40 physicians and guests present.

During the afternoon a program of sports was enjoyed. A steak dinner was served at 7:00 p.m., after which bridge was played. During the dinner and evening, Miss Rosemary Wolf, pianist, and Miss Viola Leva, accordionist, entertained the guests \*

presented under the auspices of the Saranac Lake Society for the Control of Tuberculosis, headed by Dr. John N. Hayes and Dr. Francis B. Trudeau \*

#### Kings County

at po  
July 1, has been announced by Dr. Jean A. Curran, president of the College.

Retiring after many years of service as professors and executive officers of their respective departments are Dr. Tasker Howard, Professor of Medicine, who joined the faculty of the College in 1910 as an instructor in physical diagnosis, Dr. Edgar D. Congdon, professor since 1932 and executive officer of anatomy, who following service in and Siam, and served as professor of gest current tenure College.

Succeeding these retiring professors as heads of the departments are Dr. William Dock, professor of medicine at the University of Southern California, who will become the College's first full-time professor of medicine in its eighty-three years' history, Dr. Edward Muntwyler, professor of experimental biochemistry at the School of Medicine at Western Reserve University, who will be professor and execu-

tive officer of the Department of Chemistry; and Dr. James B. Hamilton, associate professor of School of and executive

California Dr. Dock, who is a graduate of Rush Medical College in Chicago, was professor of pathology at Cornell University Medical College. From 1926 to 1931 he was on the faculty at Stanford University Medical School, first as an instructor and then as associate professor of medicine, 1929-1936, and as professor of pathology, 1936-1931.

Dr. Hamilton, before going to the University of Missouri School of Medicine, was assistant professor of anatomy at the Yale University School of Medicine.

Dr. Muntwyler first joined the faculty of the School of Medicine of the Western Reserve University in 1927, progressing steadily until becoming professor of experimental biochemistry in 1943.

Another new appointment is that of Dr. Fred L. Moore, who has returned to the staff of the Long Island College of Medicine after two years' absence to us . . . social . . . ment.

Dr. Moore has been director of the Division of Public Health Studies of the Commonwealth Fund for the past two years. He originally joined the staff of the College in 1939 as associate professor of the Department of Preventive Medicine and Community Health and was promoted to the professorship. In his new capacity he will serve also as Medical Director of the Polhemus Clinic of the Long Island College Hospital, in charge of the outpatient department of the hospital.

Other appointments of professorial rank for the year commencing July 1 are: Dr. E. J. Tiffany from assistant professor to associate professor of the department of bacteriology, Dr. F. E. Mallon from instructor to assistant clinical professor in the department of ophthalmology, and Dr. Charles A. Hargitt, Dr. E. Clifford Place, and Dr. Michael Buonaguro, newly appointed to the faculty of the College as assistant clinical professors in the department of ophthalmology, Dr. Emanuel Mendelson, from assistant clinical professor to clinical professor in the department of radiology; and Dr. F. Paul Ansbro, a special lecturer, to assistant clinical professor (anesthesiology) in the department of surgery.

#### Madison County

The JOURNAL is pleased to quote in full the following special bulletin which it received from Headquarters of the European Theater of Operations of the U. S. Army:

"For his excellent work in commanding a company of medical soldiers, Major Charles E. Tegtmeyer, of Hamilton, was recently awarded the Legion of Merit in England. Last July, as a captain in the Medical Corps, he was awarded the Silver Star for exceptional bravery in action.

"The Legion of Merit was won for his work in . . . The citation states, . . . of the North African . . . conceived and de- . . . for the transmittal of vital medical supplies from ship to shore, which has been accepted as standard equipment."

"Major Tegtmeyer has served beyond the capacity of an administering physician. During the early stages of the North African campaign, he reorganized a defunct French hospital. During a battle in Algeria he organized an ambulance service of captured vehicles. Where the Engineers were not available he supervised the building of a road across a river which provided the only means of withdrawal to one of the combat teams.

"The citation states, in closing, 'Major Tegtmeyer was a great inspiration and benefit to all his associates and contributed materially to the combat success of his organization.'"

#### Monroe County

Honors were won by four physicians and one layman at the annual meeting of the Rochester Academy of Medicine on May 2, at which Dr. John J. Finigan was elected president.

Dr. Charles B. F. Gibbs, retiring head of the Academy, presented the Paine Drug Company prize of \$100 to Dr. John H. Remington, who read his prize paper on "Amino Acid Alimentation." Dr. Remington, formerly a member of the pathologic department at the School of Medicine and Dentistry of the University of Rochester, is now on fellowship at the Mayo Clinic in Rochester, Minnesota.

Dr. Benedict Favata, assistant resident in surgery at Strong Memorial Hospital, won the Taylor Instrument Company's annual award of \$100 for his paper on "Fixation of Skin Grafts by Thrombin-Plasma Adhesion."

The Albert David Kaiser medal for 1944 was presented to Dr. James Knight Quigley for his work as head of a committee credited with influencing the decline in maternal mortality in the State.

Dr. William W. Percy, executive director of the Academy of Medicine, was given a citation for his work in that capacity in the last seven years.

Only layman to receive a citation, Al Sigl, Rochester *Times-Union* newscaster, was honored for his efforts in organizing and supervising the Legion of Blood Donors. The Legion now has a membership of 600 and more than 5,000 blood donations have been given in the past seven years. Award winners were presented to Dr. Gibbs by Dr. Shirley R. Snow, Jr.

Officers named at the meeting are: vice-president, Dr. Harold H. Baker; secretary, Dr. John L. Mercer; treasurer, Dr. George H. Gage; and assistant treasurer, Dr. Lyman C. Boynton. Elected trustees for three years were Drs. George E. Sanders, W. J. Merle Scott, and Shirley R. Snow, Jr.\*

Child health is the theme of a series of radio broadcasts which began over WHAM July 1 under the auspices of the county society.

Dr. Morris Fishbein, editor of the *J.A.M.A.*, opened the series with a discussion on "The Child as Key to Destiny and Future of America." Remaining lectures in the series will include:

Dr. John Aikman, Rochester, July 15, "Accident Prevention."

Dr. Paul A. Lembcke, Rochester, July 22, "The Child Hygiene Program of the New York State Department of Health, including E.M.I.C. Service."

Dr. Exie E. Welsch, Rochester, August 5, "Mental Health of Child" (dramatic presentation).

Dr. William L. Bradford, Rochester, August 12,

"Important Diseases Prevalent in Summer to Which Children Are Especially Susceptible—Poliomyelitis."

Dr. Jerome Glaser, Rochester, August 19, "Forms of Allergy in Children and Infants."

Dr. John Merrell Parker, Rochester, August 26, "Modern Aspects of Nutrition of Infant and Child."

#### Nassau County

Dr. Louis H. Bauer, of Rockville Centre, was elected to a five-year term as a member of the board of trustees of the American Medical Association at the final meeting of the House of Delegates at the annual session of the Association in Chicago.

Dr. Bauer succeeds Dr. Roger I. Lee, of Boston, who was made president-elect of the association.\*

#### New York County

Neuropsychiatric breakdowns among U.S. Army Air Force fliers are "the exception and not the rule," Col. Walter S. Jensen, deputy air surgeon, told a meeting of the county society on May 22 at the New York Academy of Medicine.

Colonel Jensen said Americans—"the most psychology-conscious people on earth"—tended to overemphasize and "view with alarm the incidence of neuropsychiatric casualties in this war."

Actually, he said, army fliers have shown a surprising resistance to breakdowns. "In addition, laymen should recognize that the mentality of a peace-loving democracy has not been conditioned for war and, naturally, our boys will feel the impact of discipline, fear, and fatigue" more than if they had been cast in an Axis mold.

Colonel Jensen pointed to the tremendous complexity of flying a 30-ton B-17, in which 130 gadgets must be operated by men in a five-foot cube, burdened down with equipment in below-zero temperature—at the same time fighting off enemy planes and dodging flak.\*

The New York Society for Clinical Ophthalmology has elected the following officers for the year 1944-1945: president, Milton Berliner; vice-president, Lt. Comdr. Benjamin Friedman; recording Secretary, Leon Ehrlich; corresponding secretary, Benjamin Esterman; treasurer, Daniel Kravitz.

The Committee on Medical Education of the New York Academy of Medicine announces that a fellowship in research provided by Dr. Charles Mayer of New York City has been awarded to Dr. Philip Handler of Duke University.

At the thirty-eighth annual meeting of the Women's Medical Society of New York State, the following officers were elected for the year 1944-1945: president, Theresa Scanlan, Manhattan; vice-presidents, Mary E. Potter, Brooklyn, Helen Walker, Buffalo, and Sophy Page Carlucci, Endicott; treasurer, Isabel Scharnagel, Manhattan; secretary, Mary A. Jennings, Manhattan.

Members of the county society who desire copies of the 1944 edition of the *Directory of Tuberculosis*

Clinics may obtain them, without cost, from the offices of the New York Tuberculosis and Health Association, 386 Fourth Avenue, New York City.

Those members of the county society who, because of age or physical incapacity, are confined to the home front, are deeply concerned over the professional future of their colleagues in the armed forces. Inevitably they have benefited financially by their exemption from military service and they desire to contribute some part of the increment to the re-establishment of those who have left homes, loved ones, and practice in the cause of country.

After exhaustive studies to determine how this may best be accomplished, the Trustees of the Physicians Loan and Relief Fund of the Medical Society of the County of New York, under the able leadership of Dr. Nathan Ratnof, have formed a Medical Veterans' Aid Fund. From this loans will be made without interest to enable returning members in need of economic assistance to re-establish themselves in practice, train for a specialty, or undergo suitable rehabilitation in the event of disability.

Every physician who is sensible of the great role  
are  
as  
the  
are

At present this fund is a splendid ideal. With your help it will become an even more splendid fact, enabling those of us who have enjoyed the comfort and security of home throughout a great world conflict to pay some small measure of our debt to colleagues whose patriotic selflessness has helped to purchase our safety.

Send in your contribution today to Medical Veterans' Aid Fund, c/o Trustees of the Physicians Loan and Relief Fund, Medical Society of the County of New York, 2 East 103rd Street, New York 29, New York.—J. Med. Soc. Co. N. Y.

James E. Bryan, of White Plains, executive secretary of the Westchester County Medical Society, executive secretary of the County of New York. He was elected to the office of executive secretary on September 1, 1943.

Mr. Bryan has been associated with the Westchester Society since February, 1933. Previously he was lay manager of the American Institute of Homeopathy, a national medical organization with headquarters in New York. During Mr. Bryan's association with the society, the membership has increased from 100 to more than 300.

Mr. Bryan has been active in many health and welfare activities in Westchester. He has been a member of the board of directors of the Westchester Tuberculosis and Public Health Association for the past ten years and served as its president in 1940 and 1941.

During the war period he has served as deputy director of the Emergency Medical Service in the Westchester Office of Civilian Protection, and has represented the medical society on the Division of Civilian War Services of the Westchester War Council. Mr. Bryan is also secretary of the Medical

Care Subcommittee of the Disaster Relief Committee of the Westchester Red Cross Chapter, and a member of Red Cross committees on nurse procurement, nurses' aides, home nursing, and blood donor services. He is also a member of the Health Administration Committee, the Cancer Committee, and the War Relocation Authority.

Comm. Lionel Auster has just returned to the United States after a tour of duty of almost two years in the South Pacific, where he was chief of surgery at one of the Navy's major base hospitals which officiated during most of the early Solomon Islands campaign.

A report of the surgical activities of his unit is given in the May number of the *United States Naval Medical Bulletin*, entitled "Combat Injuries in the South Pacific." His report of the syndrome of underweight, "Hydraulic Abdomen," appeared in the *Journal of the American Medical Association* in March, 1943. He is now on duty at the U. S. Naval Hospital, San Francisco.

### Oneida County

Thirty-one physicians from Utica and vicinity are now serving as advisors for draft registration at the County of Medicine.

Dr. J. J. La Manna, head of the armed forces mobile examination and induction team. Dr. H. D. MacFarland is chairman of the war-participating committee of the Oneida County Medical Society.

Dr. J. J. La Manna resumed the practice of medicine after an honorable medical discharge from the Medical Corps, having served with the 1st Station Hospital for eighteen months.

Dr. Gustav F. ... Medical Society ... ing, June 16. ... also was the re ... cocci Infections\*\*

### Orange County

The new officers of the Medical Society of the County of Orange are: president, Walter I. Neller, of Middletown; vice-president, George E. Kenny, of Port Jervis; secretary-treasurer, Earl C. Waterbury, of Newburgh; censors, Hugh M. Brewster, of Port Jervis; Homer L. Stephens, of Walden; William J. Hicks, of Middletown; and Charles W. Layne, of Newburgh.

Delegates to the State Society are T. W. Neumann, 1943-1944, of Central Valley; M. A. Stivers, 1944-1945, of Middletown. Alternates are C. B. Reed, 1943-1944, of Newburgh; and H. F. Morrison, 1944-1945, of Tuxedo.

Delegates to the First District Branch are G. R. Dempsey, of Cornwall-on-Hudson; and H. L. Stephens, of Walden.

The committees are: Public Relations, H. F. Pohlmann, *chairman*, R. L. Schmitt, T. W. Neumann, S. W. Mills, and W. E. Kelly; Public Health, N. P. Cosco, *chairman*, J. W. Walton, D. R. Gordon, F. M. Bullard, and R. F. Crabtree; Economics, H. F. Morrison, *chairman*, H. F. Mars, W. J. Hicks, C. W. Layne, H. L. Stephens, and G. R. Dempsey; War Participation, T. W. Neumann, *chairman*, H. F. Morrison, H. F. Pohlmann, C. B. Reed, M. A. Stivers, and G. E. Kenny.

On May 4 there were 240 members of the county society. Fifty-seven members are in the armed services.

### Queens County

On May 23 Dr. Vincent Mazzola, of Brooklyn, member of the Medical Grievance Committee of the State Board of Regents, outlined medical and legal racket investigations and suggested preventative and curative measures to combat professional racketeering at a meeting of the county medical society and the Queens County Bar Association.

The meeting, which was devoted to the relationship between medicine and law, was attended by 200 doctors and lawyers.

Dr. W. Guernsey Frey, Jr., of Forest Hills, president of the medical society, conducted the meeting and introduced the guest speakers, who also included Frank M. Nicolosi of East Elmhurst, president of the Bar Association, who conducted a discussion on the points outlined by Dr. Mazzola.

Mr. Nicolosi and Dr. Mazzola were guests of the officers of the medical society at a dinner in the Forest Hills Inn preceding the meeting.

A reception, with the medical society auxiliary, followed the medical-legal meeting.

The county society will hold no further meetings until fall.\*

. . .

Dr. Alexander Freed, radiation therapist at Queens General Hospital, has been appointed chairman of the speakers' bureau of the Queens County Cancer Committee. He succeeds the late Dr. John H. Barry.

Dr. Freed was formerly director of the New York City Cancer Institute, and has been engaged in cancer research for sixteen years.

The speakers' bureau is composed of physicians who lecture on cancer and cancer control to organizations requesting such talks.\*

### Rensselaer County

Miss Leah Blaisdell, member of the State Procurement and Assignment Committee for Nurses,

addressed the meeting of the county society at the Health Center in Troy on May 16.

Dr. Stephen H. Curtis reported on the Annual meeting of the State Medical Society in New York, to which he and Dr. Alson J. Hull were delegates from Rensselaer County.

Motion pictures on penicillin were shown. Dr. Richard P. Doody presided.\*

### Rockland County

Dr. Frank F. Tallman, formerly of Orangeburg, who has been Director of Mental Hygiene in the State of Michigan for the past two and one-half years, is resigning to accept the position of Commissioner of Mental Diseases in the Ohio State Department of Public Welfare, Columbus.

There are fifteen hospitals for the mentally ill, feeble-minded, and epileptic in the Division of Mental Diseases which Dr. Tallman will supervise, with a population of about 27,000 patients. In addition to his work with the hospitals, Dr. Tallman will be responsible for a receiving hospital program and state-wide program of mental hygiene.

### Schenectady County

The regular monthly meeting of the county society was held at the Shaker Ridge Golf Club on June 1. A buffet luncheon, tennis, and golf were enjoyed during the afternoon, followed by a business meeting at 5:30 p.m. After a cocktail hour at 6:30 p.m. and dinner at 7:00 p.m., Capt. Bob Bartlett spoke on arctic exploration and showed colored movies.

### Steuben County

The summer meeting of the county society was held at the Veterans Facility in Bath on June 8. Luncheon at 12:45 p.m. was followed by a business meeting at 1:30 p.m. The nursing situation in Steuben County was discussed by a representative of the Procurement and Assignment Committee for Nurses. After the business meeting the staff of the Veterans Facility presented the scientific program.

### Warren County

The new drug, penicillin, has remarkable results in certain types of infections, Lt. Comdr. R. C. Arnold reported at a dinner meeting of the Warren County Medical Society on June 15 at the Glens Falls Country Club.

Lt. Comdr. Arnold, of the United States Public Health Service, who has been doing research work on penicillin at the Marine Hospital, Staten Island, presented a detailed review of the uses and therapeutic results of the drug. He illustrated his talk with a series of slides and charts.

The drug is now available to doctors for use in certain approved types of infections and is allotted through depots. The Albany Hospital is the depot for this area.

The meeting was well attended by doctors from Warren County and many from Washington and Saratoga counties. Dr. Burke Diefendorf, president of the Warren County Medical Society, presided and introduced the speaker. Following the program a general discussion was held.

### Westchester County

Dr. Richard Charlton, of Bronxville, received the James Ewing Award of the Westchester Medical Society "as a token of recognition and commendation for distinguished service to the people and the medical profession of Westchester, contributing to

the understanding and control of malignant disease."

The award of the society's only scientific honor was made at a meeting in New York Hospital, Westchester Division, on May 16.

. . .

Dr. Vincent J. Maida, who began service in the Army as a first lieutenant in October, 1942, has received a medical discharge and has resumed the practice of medicine in Mount Vernon.\*

. . .

Several Westchester County newspapers recently carried the following editorial:

"During his term of service as Executive Secretary of the Westchester County Medical Society, James E. Bryan has brought to that organization the ability of one trained in organization and particularly in the fine art of making tech-

nical and professional problems of interest to the general public. Thus, during his twelve years of labor in the Westchester vineyards he has established a remarkably fine contact between the profession he represents and the public which they serve.

"Within the Society itself his efforts were largely responsible for increase of membership from 480 to 850 and the Society, despite absence of some 300 members in military service, is today in excellent condition. The standard of ethical conduct has been maintained, an unusually interesting *Westchester Medical Bulletin* has been issued monthly under Mr. Bryan's editorship, and there has been a growing understanding of the essential relationship which must exist between physician and patient in these trying days of shortage of medical and nursing personnel.

"Now that Mr. Bryan resigns to accept a similar post of larger scope with the Medical Society of the County of New York, it is both pertinent and timely to mention that his services will be sorely missed in Westchester. We trust the Society will be able to obtain as a successor one equally energetic and able, although we realize such an executive will not be easy to find. And with Mr. Bryan, as he leaves this Fall for his new duties, will go appreciation from both the medical profession and the public of Westchester for a difficult task well performed."

### DIRECTORY OF MEDICAL SPECIALISTS WILL HAVE NEW EDITION

The third edition of the *Directory of Medical Specialists*, listing names and biographic data of all men certified by the fifteen American boards, is to be published early in 1945. Collection of biographical data of the diplomates certified since the 1942 edition and revision of the older listings are now going forward rapidly. Diplomates are requested to make prompt return of notices regarding their

biographies as soon as possible after receiving the proper forms from the publication office soon to be mailed to them. The directory is published under the direction of the Advisory Board for Medical Specialties by the A. N. Marquis Company, 919 North Michigan Avenue, Chicago 11. Dr. Paul Titus, 1015 Highland Building, Pittsburgh 6, is the directing editor.—*J.A.M.A., June 3, 1944*

# DID WARTIME PRACTICE FIND YOU INADEQUATELY EQUIPPED?

Medical practice on our home front has demonstrated a lot of things the past two years—notably, the indomitable will to-do and the self-imposed personal sacrifices of physician while bearing their share of the greatly increased load.

With more patients to care for daily, presenting new problems and requirements, perhaps you, like thousands of your colleagues, sought additional office equipment with which to facilitate the work and help you maintain a thoroughly efficient professional service. Unfortunately, as you know wartime restrictions on manufacture made it practically impossible to obtain this equipment.

But now that the War Production Board sanctions the purchase of equipment for civilian practice, you may resume planning for your particular needs. And if it's an office x-ray unit you have in mind, or an Inductotherm, ultraviolet lamp, phototherapy lamp, extremity baker, or electrocardiograph ask us for information on today's popular G-E designs for discriminating physicians.

To place your order now for some future—yes, even postwar delivery, may ultimately prove good judgment on your part.

Let us help you to reach a decision. Write Dept. C17.

## Hospital Association Names New Council Secretaries

THE American Hospital Association announces the appointment of two new Council secretaries.

Dr. Hugo V. Hullerman will be secretary of the Council on Professional Practice, which coordinates matters of a professional nature in hospitals. Its scope covers affairs dealing with medical service, nursing, dietetics, social service, x-ray, physical therapy, and related subjects.

Until his resignation to assume his new duties with the American Hospital Association, Dr. Hullerman was chief of the division of maternal and child hygiene of the Illinois Department of Health at Springfield. A graduate of the University of Minne-

sota Medical School, Dr. Hullerman received a master of science degree in public health at the University of Michigan in 1938.

Hazen Dick is the newly appointed secretary of the Association's Council on Administrative Practice. This council correlates for association members information of such general administrative fields as hospital economics, admission and collection procedure, personnel relations, accounting, and similar management responsibilities. Mr. Dick has been administrator of both the Louisville, Kentucky, General Hospital and Waverly Hills Sanatorium in Kentucky.

## Henry Street Nurse Service Appoints Director

APPOINTMENT of Miss Marian G. Randall, nationally known leader in the field of public health nursing, as director of the Henry Street Visiting Nurse Service of New York, effective June 1, has been announced by the board of directors of that organization. Miss Elisabeth C. Phillips, acting director, will resume her former position as assistant director.

Miss Randall served as assistant director of the Henry Street Visiting Nurse Service, in charge of records and statistics, from 1938 to 1941, when she left to take a wartime position as principal nursing consultant in the U.S. Public Health Service, assigned to the Medical Division of the U.S. Office of Civilian Defense, Washington, D.C. Since completion of this assignment, she has been making a study of prepayment plans for nursing service for the Associated Hospital Service of New York.

In addition to practical experience as a public health nurse in both official and private agencies, Miss Randall has written extensively for various professional journals. From 1930 to 1937, she was a member of the research staff of the Milbank Memorial Fund, for which she conducted a series of administrative studies in public health nursing (rural and urban). She is author of a book, *Personnel Practice in Public Health Nursing in Official Agencies*, published by the Macmillan Company, based on data collected on her visits to city and state health departments in all sections of the United States under auspices of the National Organization for Public Health Nursing.

Miss Randall was graduated from the Samaritan Hospital School of Nursing in Troy, New York. She received her B.S. degree and a certificate in supervision and administration in public health nursing from Teachers College, Columbia University, where she subsequently served as special instructor.

## Army Nurse Corps Strength to Be 50,000

THE authorized strength of the Army Nurse Corps has been established at 50,000, according to an announcement of the War Department reported in the May, 1944, issue of *Public Health Nursing* and in the June, 1944, *American Journal of Nursing*.

This is a ceiling. Actual appointment of nurses will be determined by the needs of the Army in relation to casualties, and by the rate at which civilian nurses are declared available by the Pro-

curement and Assignment Service of the War Manpower Commission.

"The needs of the Medical Department fluctuate with the needs of the Army," Major General Norman Kirk, Surgeon General, U.S. Army, has stated. "The needs of the Army depend on the number of casualties and the number of casualties cannot be known until we have met the enemy for the last time."

*Designed*  
to ASSIST  
the PATIENT

THE "RAMSES"\* Diaphragm Introducer, designed after consultation with gynecologists, engages the rim of the "RAMSES" Flexible Cushioned Diaphragm at two points, shaping it into an elongated oval, thus enabling it to pass readily into the vagina. By providing complete control over the direction of travel, the "RAMSES" Diaphragm Introducer assures proper and accurate placement of the diaphragm.

1. The wide, blunt tip of the "RAMSES" Diaphragm Introducer is designed to prevent even the remote chance of accidental penetration of the uterus during insertion of the diaphragm

2. Made of easily cleansed plastic, the "RAMSES" Diaphragm Introducer has no minute crevices to harbour bacterial growth—no sharp projections to cause possible vaginal injury

3. The broad, rounded hooked end of the "RAMSES" Diaphragm Introducer—used for diaphragm removal—guards against possible entry into the urethra

Your patients obtain the "RAMSES" Diaphragm Introducer when you specify the "RAMSES" Physicians Prescriptions Packet No. 501.

"RAMSES" Gynecological Products are suggested for use under the guidance of a physician only. They are available through recognized pharmacies.

### Improvements

The "Société des 40 Hommes et 8 Chevaux" of Voiture 463 has presented an oxygen therapy unit to the Champlain Valley Hospital in Plattsburg for use in medical cases involving the respiratory system.

The presentation was made to Rev. Sister Mary Patricia, R.N., superintendent of the Hospital, on behalf of the Society of "40 and 8" by Chef de Gard Harry Neverett, past Chef de Gard Jack Goetz, and Voyageur L. H. Coulbron.\*

As the first step toward a contemplated expenditure of \$2,000 by Syracuse Post 41, American Legion, to equip a children's heart clinic in Memorial Hospital in Syracuse on May 15, Dr. Patrick H. O'Hara, commander of the post, presented a check for \$823.38 for x-ray equipment to Dr. J. G. F. Hiss, who is organizing the clinic.

Formation of the clinic will be part of a four-county campaign against rheumatic fever and heart disease sponsored by the State Department of Health and the State Medical Society. The campaign covers Onondaga, Cortland, Cayuga, and Oswego counties.

The clinic will also serve as a demonstration center, Dr. Hiss said.

Members of the University of Syracuse College of Medicine on the committee for the clinic, besides Dr. Hiss, include Dr. Brewster C. Doust and Dr. O. W. H. Mitchell.\*

Several pieces of new equipment for the Brooks Hospital in Dunkirk have arrived there and are ready for use. The instruments are gifts of the women's auxiliary of the hospital.

The equipment includes an otoscope, an ophthalmoscope, two Burdick bakers, and a Padgett dermatome.\*

Work on the new \$336,000 maternity addition to Mercy Hospital, Hempstead, was started on June 8 following ground-breaking ceremonies on the site the day before. The project will be completed before winter, it is expected.

Representatives of the church, the hospital, and various governmental agencies took part in the ceremonies that marked the start of the wartime construction job that will be done with the aid of the Federal Works Agency.\*

### At the Helm

G. Beekman Hoppin, of Syosset, was re-elected for his seventh term as president of the Nassau Hospital Association at its meeting in Mineola on May 23.

Miss Mildred Constantine, superintendent of the Amsterdam City Hospital, was elected president of the Northeastern Hospital Association at the annual meeting held on June 1 in Albany. Other officers chosen were Mrs. Helen Warren, Samaritan Hospital, Troy, vice-president, and Miss Gertrude Duncan, Ellis Hospital, Schenectady, Secretary-treasurer.

Dr. Frederick McCurdy, head of the State Department of Hospitals for the Mentally Ill, was the guest speaker at luncheon.\*

At the annual meeting of the staff of the Eastern Long Island Hospital Dr. J. Mott Heath, of Greenport, was elected chief of staff. Dr. Donald Currie, of Shelter Island, was elected secretary and head of the x-ray department of the hospital. Dr. Hans Joergensen, Dr. George Bergmann, and Dr. Heath were elected as members of the executive committee.\*

Dr. Roswell D. Johnson has arrived in Coopers-town, to begin his duties at Bassett Hospital, where he will be associated with Dr. Marjorie F. Murray in pediatrics and will direct special work in hematology.

Dr. Johnson graduated from the University of Iowa in 1938, interned in medicine at the Henry

Ford Hospital, Detroit, and in pediatrics at Yale University School of Medicine, New Haven, Connecticut. He served as assistant resident at Strong Memorial Hospital, Rochester, and as resident in New Haven Hospital children's clinic, where he had been on the full-time staff for two years.\*

S. Chester Fazio, superintendent of the Easton, Pennsylvania, Hospital for the last four and a half years, has been appointed superintendent of St. John's Riverside Hospital in Yonkers.

Mr. Fazio succeeds Captain Harry H. Warfield who died February 5.

Mr. Fazio served as a hospital superintendent in the U.S. Army in World War I and was associated with the Beekman Hospital in New York City and the Brooklyn Hospital before becoming superintendent of the Rockaway Beach Hospital in 1923, a post he held for seventeen years.\*

The board of directors of the Caledonian Hospital in Brooklyn has presented to the hospital a portrait of the institution's superintendent, Nora E. Young.

Miss Young has been superintendent since 1918, two years after the institution was granted its charter. She has seen it grow from a small twenty-bed hospital to the present modern one hundred and thirty-bed building.

Presentation of the portrait, which will hang in the hospital board room, was made by Supreme Court Justice Lewis L. Fawcett and was accepted by Donald G. C. Sinclair, president of the hospital. It was painted by Jean Spencer.\*

Dr. B. C. Tillotson, of Fort Edward, was elected president of the Glens Falls Hospital staff at its annual meeting. He succeeds Dr. John H. Sheldon and has been acting president since the former enlisted in the Navy last winter.

Dr. Edward J. Fitzgerald was elected vice-president, and Dr. W. W. Bowen was re-elected secretary-treasurer.\*

. . .

Dr. George F. Etling assumed his duties on May 15 as assistant director of the Rome State School, succeeding the late Dr. Maxwell C. Montgomery.\*

. . .

Recommendations of the Flushing Hospital medical board that 182 doctors be appointed to the hospital's consulting staff for the ensuing year were approved in May by the board of trustees.

Seventy-three of the doctors are serving with the armed forces and their posts are being held for them for the duration.

In addition, a courtesy staff of eighty-one physicians, twenty-six of whom are in the armed forces, was also named.

Heads of the various departments were re-appointed. They include Dr. J. S. Thomas, director of surgery; Dr. G. J. Lawrence, director of gynecology and obstetrics; Dr. Johnston MacLeod, director of medicine; Dr. W. C. A. Steffen, director of the dental department.

Dr. C. H. Ellard was named chief of the outpatient clinic in surgery; Dr. D. J. Swan, chief of the outpatient clinic in medical treatment; Dr. S. L. Mitchell, chief of the outpatient clinic in

gynecology and obstetrics; Dr. Emanuel Fletcher and Dr. Benjamin Goldsmith, chiefs of the outpatient clinic in pediatrics; Dr. E. A. Goode, chief of the outpatient clinic in otolaryngology; Dr. K. H. Houck, chief of the neurology clinic; and Dr. Thomas D'Angelo, chief of the outpatient clinic in ophthalmology.

Other appointments include:

Dr. Frederick Courten, Dr. J. C. McCauley, Jr., orthopaedists; Dr. Cameron Duncan, Dr. Charles A. Gordon, obstetricians; Dr. Charles H. Smith, pediatrician; Dr. Arthur S. Wilson, rhinologist and laryngologist; Dr. A. B. Reese, ophthalmologist; Dr. H. M. Imboden and Dr. F. M. Law, roentgenologists; Dr. F. N. Dealy, Dr. Donald Gordon, Dr. B. G. Story, and Dr. J. N. Wickham, surgeons.

Dr. A. S. W. Touroff, thoracic surgeon; Dr. H. Easton McMahon, cardiologist; Dr. James G. Dwyer, Dr. Isodore Friesner, otologists; Dr. James L. Joughin, neurologist; Dr. Thomas H. Cherry, gynecologist; Dr. J. J. Rothwell, dermatologist; Dr. Oswald Lowsley, Dr. Fedor Senger, Dr. J. H. Morton, genitourinary surgeons; Dr. Arthur S. Wilson, bronchoscopist; Dr. Fred W. Steward, pathologist; Dr. Lewis D. Stevenson, neuropathologist; Dr. Horace King, Dr. Herbert D. Ayers, dental surgeons; Dr. Harold S. Vaughn, oral surgeon; Dr. Abraham Braunstein, tuberculosis, and Dr. J. F. Dick and Dr. F. B. Wood, physicians emeritus.

Dr. Leonard Goldman, radium therapist; Dr. Ralph Herendeen, roentgenologist; Dr. Evelyn Apogi, director of anesthesia; Dr. Jacob Werne, pathologist; Dr. K. H. Houck, attending neurologist; Dr. J. H. Siris, neurosurgeon; Dr. C. N. Baker, director of the dispensary, and Dr. A. E. Donnelly and Dr. Charles Miller, attending dermatologists.\*

## Newsy Notes

The Bronx Area Station Hospital, formerly Lebanon Hospital, was dedicated by the Army on June 7. The hospital was taken over in July last year and is being used to care for transient Army personnel.\*

. . .

The late Norman L. Noteman, of New Rochelle, in his will, set up a fund for the use of New Rochelle Hospital to be known as "the Noteman Memorial Fund."\*

. . .

On June 5, Maj. Gen. T. A. Terry, commanding general of the Second Service Command, dedicated the Staten Island Area Station Hospital, an Army Service Force installation, at New Dorp Beach, Staten Island.

Col. Ralph Cudlipp, commanding medical officer of the post, presided over the ceremonies, which were attended by four hundred persons, including members of the Red Cross, Wacs, and enlisted men.

The hospital, which has been operating for several months, provides medical and surgical treatment for sick and injured soldiers from units in the metropolitan area. If called upon, General Terry said, it could take care of overseas casualties.

After the dedication, at which Borough President Joseph A. Palma and Dr. Edward Bernecker, Com-

missioner of Hospitals, also spoke, General Terry and his guests toured the twenty buildings that make up the hospital.\*

. . .

Forty-four women volunteers who will serve in hospital libraries here by delivering books to patients received certificates of graduation on June 7 from a training course given by the hospital library bureau of the United Hospital Fund of New York. Roy E. Larsen, president of the fund, presented the certificates.

Two hundred volunteers are needed immediately for the summer months, according to Mrs. Louise Heinze, director of the bureau. Women who can give one full day or two half days a week are urged to register at the fund's office. After training on the job they will be enrolled in the regular course in October.

The bureau's training course is given three times a year. Three hundred and fifty women have completed it and are serving in patients' libraries in fifty-nine city and voluntary hospitals affiliated with the fund.

A hospital library volunteer visits each patient twice a week, wheeling a book cart loaded with novels, current fiction, and nonfiction, and magazines for men and women. On an average day a volunteer gives out books to about sixty patients.

# injectable vitamin B complex!

THE FIVE IMPORTANT FACTORS  
IN STABLE

*Instantly Soluble*  
FORM

As a result of chemical investigations still further progress in vitamin therapy has been made. Now in one ampul there are available the following synthetic factors:

Thiamine hydrochloride (vitamin B <sub>1</sub> )	10 mg
Riboflavin (vitamin B <sub>2</sub> )	5 mg
Pyridoxine hydrochloride (vitamin B <sub>6</sub> )	5 mg
Calcium pantothenate	5 mg
Niacinamide (nicotinic acid amide)	50 mg

Supplied in boxes of 3 and 10 ampuls

Dissolve in 2 cc. of sterile distilled water

If increased vitamin B<sub>1</sub> is desired use as solvent any Betaxin parenteral solution (available in 10 cc. vials containing in each 1 cc. either 10 mg. or 25 mg., or 50 mg. or 100 mg.)

Betasynplex may be administered

*subcutaneously*

*intramuscularly*

[Continued from page 1598]

Some of the women trained in the course serve as Red Cross Gray Ladies in government hospitals. The majority, however, have qualified only for work in civilian hospitals. Organizations cooperating with the bureau include the American Red Cross, the American Women's Voluntary Services, the Civilian Defense Volunteer Office, the city's Department of Hospitals, and the New York Public Library.\*

A reception and tea held in the Nurses' Residence on May 16 marked the one hundred and seventy-third anniversary of New York Hospital. The celebration also marked the granting of a charter to the institution by King George III in 1771.\*

Initial subscriptions of \$17,700 by nine donors to establish the second floor in the new wing of Northern Westchester Hospital as a memorial to the late Horace Eddy Robinson, of Pleasantville, and one of \$25,000 toward the establishment of the third floor wing as a memorial to Dr. Charles F. Chapman of Mount Kisco, have been announced by F. Wilder Bellamy, chairman of the special gifts committee in the hospital's \$500,000 building fund program.\*

The annual awards of the United Hospital Fund of New York were presented at Carnegie Hall on

May 18 to 2,200 men and women who have served as volunteers in Manhattan and Bronx hospitals during the last year. Enamel pins were presented to those who served more than the minimum requirement of 150 hours, and gold bars were given to others who have totaled 500 hours since the volunteer system was instituted May 1, 1940.\*

The Women's Organization for the American Merchant Marine recently presented a check for \$1,000 to Howard S. Cullman, president of the hospital, for the re-endowment of two beds for one year. This was the third time the organization had made such an endowment.

The club's beds will bear a small plaque honoring the donors and will be devoted to wounded and sick American merchant seamen who are referred to the hospital by the Seamen's Church Institute of New York. The Beekman institution, because of its proximity to the East River piers, has treated hundreds of such seamen.\*

The Associated Hospital Service of New York now issues group contracts providing care in hospital wards at a cost of 56 cents a month for individuals and \$1.32 a month for an entire family. The new plan, which is sold only on a payroll deduction basis, is designed for persons of low income who cannot afford the service's regular Blue Cross Plan, providing hospital care in semiprivate rooms.

#### KENTUCKY WOMAN GETS DANA MEDAL

The Leslie Dana Gold Medal, awarded annually for outstanding achievements in the prevention of blindness and the conservation of vision, will be presented this year to Miss Linda Neville of Lexington, Kentucky, it is announced by the National Society for the Prevention of Blindness.

Miss Neville is the founder of the Kentucky Society for the Prevention of Blindness, which is virtually a one-woman organization, and she is known in her home state as "the angel of Kentucky."

During the past 40 years, she has utilized her Bryn Mawr education, taken advantage of her social connections, and spent practically her entire inheritance in order to bring sight to hundreds of babies, young children, and adults from the poverty-stricken mountain districts of Kentucky, who needed medical care or eye surgery.

Miss Neville, who is now 70 years old, was born in the same house which has served as the head-

quarters for her prevention-of-blindness activities. At least 1,000 persons have received skilled medical care and have been saved from the doom of darkness through her intercession.

Selection of the recipient of the Leslie Dana Gold Medal is made by the St. Louis Society for the Blind, through which the medal is offered by Mr. Leslie Dana of St. Louis. This highly prized token of recognition in the field of public health is given upon the recommendation of the Association for Research in Ophthalmology.

The conditions of the Leslie Dana Medal award set forth that it is to be made for "long meritorious service in the conservation of vision in the prevention and cure of diseases dangerous to eyesight; research and instruction in ophthalmology and allied subjects; social service for the control of eye diseases; and special discoveries in the domain of general science or medicine of exceptional importance in conservation of vision."

#### AMERICAN BOARD OF OPHTHALMOLOGY ANNOUNCES 1945 EXAMINATIONS

The American Board of Ophthalmology has announced the approximate dates for its 1945 examinations.

In Los Angeles the examination will be held during the Midwinter Course if the number of applications warrant it. The dead line for applications is October 1, 1944. The examinations in New York City will be held in June, the exact date to be an-

nounced later. The dead line for applications is December 1, 1944. The date of the examinations in Chicago has not been set; the dead line for applications is April 1, 1945.

All examination dates are contingent on war and transportation conditions. Application blanks can be obtained from the American Board of Ophthalmology, Cape Cottage, Maine.

R

# Pediforme

## FOOTWEAR

## FILLING YOUR VIEW OF ECONOMY

In corrective footwear, wearing quality is not the only consideration, naturally—but no physician will willingly "sell" a patient on shoes that may not last long enough to function properly nor wear well over sufficient period of time to make them economical as well as beneficial.

Both in construction and in material, Pediforme shoes are made to provide "longevity" in all the important factors required of preventive and corrective footwear. In spite of the present, greater purchasing power, we still believe the average American wants a full dollar's worth as well as the best that money can buy.

## THERAPEUTIC TEAMWORK

### Vitamin "B" Complex fortified with Vitamin "C"

Research has shown that vitamins B and C appear to work as a team in effecting beneficial changes in cellular physiology. This was clinically manifested by improvement in pathology of the upper respiratory mucosa and the retina when the two vitamins were given together. When only one was used, this favorable reaction did not occur.

Vitamin "B" Soluble (Walker) is derived from brewers yeast—its potency increased so that three capsules meet the minimum daily needs for vitamin B factors recommended by the U. S. Government.

Professional samples sent on request to Myron L. Walker Co. Inc., Mount Vernon, New York.

# Health News

## Public Health Officials Hold Conference

The Annual Conference of Health Officers and Public Health Nurses was held June 27 and 28 at the Grand Union Hotel, Saratoga Springs.

The opening address was given by Dr. Edward S. Godfrey, Jr., State Commissioner of Health, followed by a talk on health in England by Arthur Massey, M.D., medical officer of health, Coventry, England.

"The Role of the Practicing Physician in the Improvement of Medical Care in the State of New York" was the subject of an address by Herbert H. Bauckus, M.D., President of the Medical Society of the State of New York.

Maj. John H. Dingle, M.D., commissioner on acute respiratory diseases, Station Hospital No. 2, Fort Bragg, N.C., opened the afternoon session with a discussion on "Atypical Pneumonia," followed by talks by William T. Wells, associate professor of research in air-borne infections, University of Pennsylvania, and Dr. R. E. Dyer, director, National Institute of Health, Bethesda, Maryland.

The Wednesday morning session was opened by Dr. Foster Kennedy, professor of neurology, Cornell University Medical College, who spoke on "Nervous Conditions Associated with Warfare," followed by Dr. Martha M. Eliot, associate chief, Children's Bureau, United States Department of Labor, Washington, D.C. The title of Dr. Eliot's address was "Problems of Infant Mortality."

Recent introduction of rapid treatments for early syphilis marks a major step forward in the fight against the disease, Dr. George W. Baehr, member of the New York City Health Council, said in an address before the group.

Declaring that thousands of syphilis patients have been treated in hospitals in all parts of the country, Dr. Baehr said "slavish adherence" to the slower methods of therapy has been largely responsible for failure to eradicate the disease.

"With the introduction of penicillin, the picture has changed," he stated. "Eighty to 90 per cent of all patients with early syphilis can be rendered non-infectious and perhaps cured within a week. Sufficient time has not elapsed to speak positively of a cure, but the results are most encouraging."

Dr. Foster Kennedy told delegates that "perhaps the most important weapon against nervous breakdown in war is a sense of unity with your immediate group." Dr. Kennedy said "the herd instinct has been described as important in helping each individual to do his task," and added:

"We know from this war that each man's social reputation is important to himself . . . . In Britain it has never been 'good form' to show over-much emotion; this is a precious asset when bombs are falling. Of course, each man is afraid, but, if he is never allowed to show fear and if he shows little fear to others, panic is not spread. Discipline, to be perfect, must be within—only in lesser terms from without."

## Use of Penicillin in Early Syphilis

Large-scale use of penicillin in the treatment of early syphilis is being undertaken by the U.S. Public Health Service, the Federal Security Agency, and a number of State health departments, Medical

Director J. R. Heller, Jr., chief of the P.H.S. Venereal Disease Division, announced on June 15. Selected patients with early syphilis will receive penicillin in rapid-treatment centers, of which there are more than fifty in the United States. Thirty-six centers in eighteen States are already participating in the penicillin program.

The rapid treatment centers are special hospitals that have been established within the last two years as part of the national venereal disease control program. To date approximately 20,000 patients have been admitted to the centers and have been treated for syphilis and gonorrhea with new intensive methods. Penicillin already has been used successfully at the rapid-treatment centers for treating gonorrhea cases that did not respond to sulfa drugs. Studies of the effectiveness of penicillin in the treatment of syphilis will be conducted by the Public Health Service in cooperation with the National Research Council.

"This program of penicillin therapy for syphilis is a research as well as a treatment program," Dr. Heller said. "The effectiveness of penicillin in the treatment of syphilis has not been fully evaluated. However, evidence of its possibilities, following the original treatment of syphilis patients by Public Health Service physicians at Staten Island in 1943, is sufficient to warrant its large-scale use in the interest of public health. If these studies prove that penicillin is as effective as everyone hopes, we will be armed with a powerful new weapon in the national fight against syphilis. It is of interest that about one-third of all the syphilis patients admitted to rapid-treatment centers are infected also with gonorrhea. Penicillin has already proved its value in treating gonorrhea. If it should prove equally as effective in treating syphilis it would be possible, for the first time in medical history, to treat patients with both these venereal diseases with a single drug."

The news that penicillin had been used with preliminary success to treat syphilis was first announced in October, 1943, by Senior Surgeon J. F. Mahoney, U.S. Public Health Service Venereal Disease Research Laboratories, U.S. Marine Hospital, Stapleton, Staten Island, New York. Three of the original patients treated by Dr. Mahoney and his associates have been under observation for nearly a year; to date, they remain free of any symptoms of the disease.

Since Dr. Mahoney began his research, additional studies have been conducted by the Army, the Navy, and the U.S.P.H.S. in collaboration with the Penicillin Panel of the National Research Council. More than 1,000 patients with syphilis in all stages have been treated with penicillin in these studies. The drug has an immediate effect on syphilis of all types, but additional time must pass before permanence of results can be judged, according to Dr. Heller.

Most of the patients selected for penicillin treatment in the P.H.S. program will be persons with early untreated syphilis who can be re-examined regularly for a period of six months or a year. Two schedules of penicillin therapy are being considered in the U.S.P.H.S. program—a four-day schedule and an eight-day schedule.

State rapid-treatment centers to which U.S.P.H.S.

# HYPERTENSION CASUALTIES

## ... Cardiac Failure

Essential hypertension regularly results in concentric hypertrophy of the left ventricle. If the hypertension persists, the hypertrophied heart eventually dilates and fails.

To aid the reduction of blood pressure quickly *without shock*—and maintain the reduction—physicians prescribe Natrico Pulvoids. This synergistic combination of vasodilators obtains full action of the nitrites, but avoids the disadvantages of the constituents when used alone.

### SYMPTOMATOLOGY

Natrico Pulvoids are especially useful in the symptomatic treatment of essential hypertension and for relief of *cardiac pain, headache, dizziness* and *tinnitus* due to arterial hypertension. Each Pulvoid contains: Potassium Nitrate, 2 grs., Sodium Nitrite 1 gr., Po. Ext. Crataegus Oxyacantha  $\frac{1}{4}$  gr., Nitroglycerin 1/250 gr. Supplied: Bottles of 100 Pulvoids.

Write Dept. 1 for samples and literature. THE DRUG PRODUCTS CO., Inc.,  
Long Island City 1, New York

# NATRICO

## PULVOIDS

*for accurate dosage  
and minimum gastric distress*

## IN IODIDE ADMINISTRATION

# ENKIDE

*Brewer*

THE OLD—messy, inconvenient liquid formula fell far short of providing accurate dosage of Potassium Iodide. Droppers differed; drops varied with size of dropper tip, the angle at which it was held, and the specific gravity or viscosity of the solution. Compare this guesswork with...

1 GRAM POTASSIUM IODIDE, U.S.P.  
(15.43 grains)  
Enteric Coated Tablets  
Supplied in bottles of 100  
on prescription only

THE NEW—accurate, controllable and less obnoxious administration of Enkide tablets when Iodide is indicated, assures less distress for patients and less possibility of skipping doses. The enteric coating minimizes gastric distress and eliminates taste. *Tablet form* makes the dose easier and more convenient to take.

Literature and samples on request.

physicians have been assigned to supervise the medical program, and which are already participating, include: San Diego, California; Denver and Pueblo, Colorado; Ocala, Wakulla, and Jacksonville, Fla.; Pineville and New Orleans, Louisiana; Ann Arbor, Michigan; Meridian and McLain, Mississippi; Albuquerque, New Mexico; Charlotte, North Carolina; Rush Springs, Oklahoma; Columbia, South Carolina (three centers); Nashville, Chattanooga, and Memphis, Tennessee; San Antonio, El Paso, and Waco, Texas; Richmond, Virginia; Seattle and Grand Mound, Washington; and Washington, D.C.

Federal Rapid Treatment Centers participating include: Birmingham, Alabama; Hot Springs, Arkansas; Pensacola, Florida; Savannah and Augusta, Georgia; Greenwood, Mississippi; St. Louis, Missouri; Durham, North Carolina; Norfolk, Virginia; Charleston, West Virginia.—*Release from the Office of War Information*

## Dental Examinations Begun in Caries-Fluorine Demonstration

As a first step in a long-range demonstration to determine the practicability of mass protection against dental caries by adding fluorine to public drinking water supplies, the New York State Department of Health recently began dental examinations of school children in the city of Newburgh which, with the city of Kingston, is collaborating in the project. These communities were selected as study and control areas, respectively, after careful consideration of many sections of the State which might be suited to such a demonstration.

The examinations in Newburgh are being made by the Department's senior dentist, who plans to make dental inspections of about 1,000 children in various age groups from 5 through 14 years. The purpose is to obtain, at the outset of the demonstration, a dental caries index which will serve as a basis for comparison with the terminal figures at the end of ten years, the length of time which must elapse before the full benefits of the water treatment are realized.

This comparative analysis will make it possible to determine any improvements which may have resulted from fluorination of the water.

It is also planned to make a pediatric investigation of a representative sample of the child population, including a general physical examination, urinalysis, and x-rays of the long bones and centers of ossification.

Procedures for these examinations are now being prepared and when they are completed, a substantial portion of the child population will be examined. All examinations will be made before the fluoride is added to the water supply.—*Health News, June 5, 1944*

## Free Penicillin Treatment of Gonorrhea

Sulfonamide-resistant gonorrheal patients may be referred for treatment with penicillin to the Central Clinic of the Bureau of Social Hygiene, New York City Department of Health, located at 130 Leonard Street, Manhattan. This announcement was made by Dr. Ernest L. Stebbins, New York City Commissioner of Health, on June 17.

Treatment for such patients may be obtained without cost, irrespective of their economic status. This service is available by appointment; telephone WO 2-6900, extension 331.

## New Boric Acid Labeling Regulation Announced by Board of Health

The New York City Board of Health at a meeting held May 31 amended the Sanitary Code sections pertaining to drugs by adding a new section (Section 127), effective June 15, 1944, requiring that labels on boric acid in the form of powder, crystals, or solutions shall contain the warning: "Caution—Not for Internal Use Except as a Mouth Wash, Eye Wash, or Douche."

## Hygiene Association Issues 1943 Report

An all-time high was reached last year in the nation's fight against the venereal diseases, but the attack must be maintained and strengthened, since gonorrhea and syphilis remain this country's most serious wartime health problems.

This information is highlighted by the American Social Hygiene Association in its annual report for 1943, issued by the Association's executive director, Dr. Charles Walter Clarke.

Although the rate "is the lowest in our military history," venereal disease is still "a leading cause of lost man days among the armed forces," Dr. Clarke states in the annual report. "Indications of increased venereal disease prevalence in civilian communities are causing anxiety among civil and military health leaders. They know that increased civilian rates are likely to be reflected in higher military rates," the report continues.

"The past year's experience again substantiated the basic fact that active, united support by the public of all measures—educational, medical, protective—directed against the venereal diseases is the key to victory against these infections," Dr. Clarke declares. "If these activities are strengthened," he says, "the new discoveries—especially the modern intensive therapy of syphilis and the penicillin treatment of gonorrhea—may make it possible, in the not too distant future, to bring venereal diseases completely under control."

Until the war is won, "the major objective of the American Social Hygiene Association must continue to be helping to keep soldiers, sailors, marines, and airmen at their posts and fit to fight, to keep workers fit to produce the instruments of war, and to protect youth in wartime," the report states in conclusion, keynoting the Association's activities for 1944.

"Unity Against VD" is the title of the Association's report. It indicates stepped-up participation by individuals and community groups in every phase of the Association's activities in 1943. The Association's medical staff members served as consultants to several Federal agencies, it is reported, and participated in the training of Army, Navy, and Public Health Service venereal disease control officers at the Army Medical School, Johns Hopkins University, Harvard University, and the Bethesda headquarters of the U.S. Public Health Service.

The Association gave guidance to one hundred and forty-five affiliated societies and helped form eleven new societies in the course of the year. The cooperation of fifty national voluntary agencies was obtained.

The American Social Hygiene Association, a participating service of the National War Fund, officially represents voluntary health agencies in carrying out the Federal government's venereal disease control program. It is teamed with the Army, Navy, U.S. Public Health Service, and the

# Woman's Auxiliary

## To the Medical Society of the State of New York

### County News

**Chautauqua County.** The quarterly meeting of the Chautauqua County Woman's Auxiliary was presided over by the new president, Mrs. Charles E. Goodell. Luncheon was served, followed by a report of the meeting of the House of Delegates of the State Woman's Auxiliary in New York City in May, by Mrs. W. Gifford Hayward. An invitation was extended to the auxiliary by Dr. and Mrs. Hilding A. Nelson for the July meeting, a picnic supper to be held at their new home, Cresthaven, overlooking Chautauqua Lake. There will be no meeting in August.

**Columbia County.** The nurses of the graduating class of the Hudson City Hospital were the guests at a very attractive tea at the home of Mrs. Lawrence J. Early. In addition to the graduating class the guests included the student nurses and faculty of the hospital, Dr. Elah Bliss and Dr. Sue H. Thompson, and Mrs. Ellen O'Reilly, of West Hurley. The house was beautifully decorated with flowers, the arrangement of white lilacs, lilies of the valley, and red tulips centering the tea table being especially lovely. Mrs. Hugh Henry, of German-town, Mrs. W. D. Collins, Mrs. O. H. Bradiey, and Mrs. R. L. Bowerhan, of Copake presided, assisted

by Mrs. C. L. Schultz, of Philmont, Mrs. R. D. Shaw, of Stottville, and Miss Elizabeth Parks.

**Oneida County.** Officers were elected at the annual meeting of the Oneida Auxiliary at a breakfast at the Yahnundasis Golf Club, with thirty-seven members in attendance. Reports of the annual meeting of the House of Delegates of the Women's Auxiliary, held in New York City, were given by the delegates, Mrs. D. D. Reals, Mrs. B. F. Golly, Mrs. F. M. Miller, Jr., Mrs. H. W. Jones, and Mrs. William Hale.

Mrs. B. F. Golly is the new president for Oneida County; the announcement was made that Mrs. F. G. Jones, the past president, had been elected to the office of treasurer in the State Society.

The next meeting will be held in October.

**Rensselaer County.** Mrs. W. W. St. John presided at the annual meeting, held in the Y.W.C.A. Luncheon was served and the officers for the coming year were elected. Mrs. J. J. Noonan is the incoming president. Reports from the officers and standing committees for both the year and the preceding month were given and tentative plans were discussed for an outing to be held in July at the Troy Country Club.

### THE BEDSIDE MANNER

One of the most important characteristics of great men in medicine who have inspired and deserved our admiration and affection is the "bedside manner." The term as used here connotes depth of learning and sincere concern for the patient, which is the only sound basis for confidence in a doctor. This "manner" has been and is seen at its best in consultation in the sickroom, for here the consultant observes meticulous consideration for his fellow practitioner, whose guest he is for the moment. There is nothing finer than this relationship in medicine.

Recently a Washington physician was quoted as saying that something should be done to prevent physicians from suggesting to patients that they have been carelessly or badly treated at the hands of a previous attendant. The implications in this statement are that doctors as a rule are unfair to each other. It can be safely said that rarely does a physician with malice aforethought disparage another practitioner in the presence of a patient. On the other hand, physicians have not always been as diligent as they might be to explain to a patient coming to them from another doctor that a sense of dissatisfaction or distrust may be based on misunderstanding or a faulty evaluation of results. Withholding a judiciously favorable comment on a colleague may really leave a physician open to serious criticism. For, as Robert Louis Stevenson observed, "One may sit in a room and listen in silence while a friend is attacked and leave the room

having more completely condemned his friend than if he had spoken."

It is not meant to suggest that malpractice should be condoned or defended but merely that physicians be extremely cautious and fair toward a previous attendant when they find themselves being credited with exceptional ability and judgment. Indiscretion is usually a boomerang. It would be too bad if it injured only the sender. Not infrequently when badly aimed or well aimed with bad intentions, it may become a dangerous instrument, resulting in damage to the patient, the doctor, and the entire medical profession. A boomerang might just as well be swung gently and carry a message of good will, to restore confidence to a doubting and unhappy patient, returning to give the sender a feeling of satisfaction in a deed well done.

Possibly the noise and confusion of the times may tend to dim the appeal of the Golden Rule. More, perhaps, than ever before we are called upon to be our brother's keeper. To serve our brother best, we must observe proper rules of conduct actively rather than passively. The Rule does not say we must not do unto others what we do not want them to do unto us but rather *do* unto others as we would have them *do* unto us. This, it would seem, is the keynote of the "manner" at the bedside as regards our fellow physicians. A fine "bedside manner" in the office, on the street, and even "off the record" is the medical man's finest attribute.—J. W. L., in *Med. Annals, District of Columbia, May, 1944*

## REVIEWED

**Reaction to Injury. Pathology for Students of Disease Based on the Functional and Morphological Responses of Tissues to Injurious Agents.** By Wiley D. Forbus, M.D. Quarto of 797 pages, illustrated. Baltimore, Williams & Wilkins Co., 1943. Cloth, \$9.00.

Two of the four parts of this work have already appeared. The other two parts are in the process of completion, and the reviewer hopes that they will soon be published. The work is intended as a text on pathology for students of disease and fulfills that purpose successfully.

The author's approach to the subject of pathology is novel. Part One is devoted to the nature and causation of disease and Part Two to the "completed treatment of the resistive action to injury." Quoting further from the preface, "the remaining two parts, one dealing with the submissive type of reaction and the other with the reaction of adaptation, are in preparation. Although it naturally would have been best to have the work appear in its completed form, the prevailing conditions make the publication of the first two parts particularly appropriate, since they constitute a clearly defined entity dealing with the infectious diseases. In its present form the book can be used satisfactorily as a text for the course in pathology for students of the second year when properly supplemented by lectures and case work. Its application to the problems of

the general practice of medicine, especially to military medicine, will be obvious from a study of the table of contents."

The author has successfully achieved his purpose and has presented the subject from a most interesting and educational point of view. The subject matter is well and appropriately illustrated; the kodachrome reproductions are particularly striking and beautiful. The reviewer looks forward with considerable expectation to the completion of this work. It may well be recommended to the clinician as well as to the laboratory worker. Certainly it is a book without which no modern laboratory library could be complete.

MAX LEDERER

**Minor Surgery.** By Frederick Christopher, M.D. Fifth edition. Octavo of 1006 pages, illustrated. Philadelphia, W. B. Saunders Co., 1944. Cloth, \$10.

The fifth edition of *Minor Surgery* has had numerous additions which greatly enhance the value of this excellent treatise. The directions for handling minor and minor-major problems are explicitly indicated and in many cases well illustrated. The book is a valuable addition to the library of the busy practitioner, who, now more than ever, is called upon to treat minor surgical problems. The bibli-

Northwest Institute of Medical Technology  
3422 E. Lake St., Minneapolis, Minn.

[Continued from page 1610]

ographies and index are adequately presented so as to facilitate ready reference to the text and further study.

IRWIN E. SIRIS

**Clinical Tropical Medicine.** By twenty-seven authors. Edited by Z. Taylor Bercovitz, M.D. Quarto of 957 pages, illustrated. New York, Paul B. Hoeber, Inc., 1944. Cloth, \$14.

This book contains a comprehensive presentation of those disease entities, both exotic and indigenous to this country, which are commonly thought of as tropical diseases.

The editor and twenty-six other authorities well known for their contributions in this field have written sections on the diarrheal diseases, helminthic diseases, and on the diseases caused by the blood protozoa, the spirochetes, rickettsiae, viruses, bacteria, and yeasts and fungi. There are also sections on the nutritional diseases, tropical snakes and poisonous insects, and on tropical hygiene and sanitation. Laboratory diagnosis is not particularly stressed, but neither is it neglected. Illustrations are numerous, clear, and informative. It is an excellent book either for text or for reference.

ELBERTON J. TIFFANY

**Essentials of Gynecology.** By Willard R. Cooke, M.D. Octavo of 474 pages, illustrated. Philadelphia, J. B. Lippincott Co., 1943. Cloth, \$6.50.

This book is primarily for the medical student and the general practitioner. It has grown out of author's extensive teaching and clinical experience.

The opening chapter is on the anatomy of the female pelvis and its contents. The illustrations of this and of most subsequent chapters are excellent and largely original. Considerable space is devoted to a consideration of extrapelvic pathology and psychologic factors affecting the patient. The general body of the text is clearly presented and concise. There is a section on both pre- and postoperative care of the patient. It does seem out of place in such a work to outline without illustration the more common gynecologic operations.

The book is an excellent guide for students and one which general practitioners will find both interesting and helpful.

ONSLow A. GORDON

**The Principles and Practice of Medicine.** Originally Written by Sir William Osler, Bart., M.D., F.R.C.P., F.R.S., Designed for the Use of Practitioners and Students of Medicine. By Henry A. Christian, M.D. Fifteenth edition. Octavo of 1,498 pages. New York, Appleton-Century Co., Inc., 1944. Cloth, \$9.50.

As one turns the pages of this fifteenth edition, the totality of the amount of material presented is impressive. Monographic handling is not possible, even in an Osler, but discussion is generally thorough, nevertheless.

The book handles well (4 1/4 pounds) and the page reads easily, the type being particularly clear. References in heavy type continue to be very valuably presented. There are many homely phrases, some from the pen of the master, but we suspect the present editor is aware of the driving power of a pat quotation.

Christian has produced his best edition. The introductory remarks dealing with psychosomatic medicine, though brief, are inspired.

No special chapters can be singled out for commendation. General excellence prevails, as always in Osler. Therapy is not bold; indeed, it is often characterized by conservatism. Penicillin, "un-

tion of this wonder drug. Uracil in goiter is discussed and appraised. Copper as a catalyst in the anemias is not considered.

ad: "growing  
ky Mountain  
and the rare  
syphilitic factor in Addison's disease is not mentioned.

The chapter on arthritis continues to be utterly inadequate and not up to standard. It is confusing, not in line with the concepts in this disease which are becoming more clear, and should be rewritten. A chart contrasting the features of the atrophic and hypertrophic types would be clarifying, and is respectfully urged.

FRANK BETHEL CROSS

**Recent Advances in**  
**tory Therapeutics.** By  
D.P.H., and E. C. Dodds. Philadelphia,  
Octavo of 412 pages, illustrated. Philadelphia,  
Blakiston Co., 1943. Cloth, \$5.50.

The recent edition of this British book brings  
to date.  
sulfur  
Kidney

A very proper allotment of space is given to diabetes, its management, and some complications. Liver function tests are covered very conservatively. Addison's disease, electroencephalography, and the hormones are briefly discussed. There is a good chapter on blood disorders. The volume continues to be interesting and useful.

A. M. BABBY

**Office Endocrinology.** By Robert B. Greenblatt, M.D. Second edition. Octavo of 243 pages, illustrated. Philadelphia, Blakiston Co., 1944.

most important in the field of endocrinology. It is a daily office practice; it is even more difficult to condense this material into a small volume. Dr. Greenblatt has done a remarkable job of selection and condensation; his presentation is clear, easily readable, and palatable for the practitioner whose limited time does not permit perusal of more voluminous texts. The references after each chapter will help those who wish more detailed information.

M. A. GOLDZIEHER

**Medical Physics.** By Otto Glasser, Ph D., Editor-in-Chief, and others. Quarto of 1,744 pages, illustrated. Chicago, Year Book Publishers, Inc., 1944. Cloth, \$18.

many to add this work to their reference library. Haden and Ponder have useful material on blood studies; Hamilton has several fine papers on blood volume, blood plasma, and lung circulation. John Talbott presents up-to-date material on the ill effects of high altitude and of excessive heat.

A. M. BABBY

## **The Diabetic Life Its Control by Diet and Insulin**

LAWRENCE—13th Edition

The war has brought many problems and some special difficulties to diabetics mainly concerned with food rationing. These are dealt with in a Wartime Supplement in this new edition. A short guide to treatment is also included. 18 Illus. 228 Pages. \$1.00 (1944)

## **Recent Advances in Medicine**

BEAUMONT & DODDS—11th Edition

Many important advances in treatment and in routine clinical and laboratory methods of diagnosis are included in this edition. The sulphonamide drugs, vitamins and a special article on Penicillin are among the new subjects presented. 43 Illus. 412 Pages. \$5.50 (1943)

## **Recent Advances in Pathology**

HADFIELD & GARROD—4th Edition

This book presents a concise account of the many advances in pathology based upon extensive research work. New material includes chapters on Vitamin Deficiency and Essential Hypertension. Section on Crush Syndrome, Extra-Renal Azotemia, Etiology of Rheumatic Fever, Cancer Research, Pathogenesis of Pneumonia, Regional Ileitis, Lipoid Pneumonia, Bronchial Adenoma, Pyelonephritis, are included. 35 Illus. 346 Pages. \$5.50 (1942)

## **Hughes' Practice of Medicine**

BURGESS GORDON—16th Edition

This book provides a concise account of various diseases, their diagnosis and treatment. It is ideally suited for reference to the essential features of each condition. Choice prescriptions are given and the essential procedures in after care are discussed. 36 Illus. 791 Pages. \$5.75 (1942)

# MEDICINE REACHES NEW HORIZONS

**T**he discovery of penicillin and of its wonderful power to successfully combat death-dealing germs has brought medicine to new heights of ability to cope with many hitherto baffling ills that beset the human body.

The intriguing story of how officials of pharmaceutical concerns gave penicillin production the "green light" and, with the invaluable aid of governmental agencies, feverishly planned for an adequate production—how mycologists, bacteriologists, chemists, and chemotherapists worked day and night—how 22 companies poured \$25,000,000 to \$30,000,000 into this enterprise—comprises a never-to-be-forgotten episode in the saga of American pharmaceutical industry.

We are proud that Roche has kept in full step with the great march of scientific and engineering progress which ere long will place the wonder drug—penicillin—in the hands of every physician . . . HOFFMANN-LA ROCHE, INC., NUTLEY 10, N. J.

# Pediforme

## FOOTWEAR

## SHOES AS THERAPEUTIC AGENTS

No doctor can ignore that shoe therapy is a major factor in the treatment of many foot disorders. In some cases, however, when further medical or surgical treatment is required, the shoes must be adjusted to conform to any changes such treatments make in the shape or size of the feet.

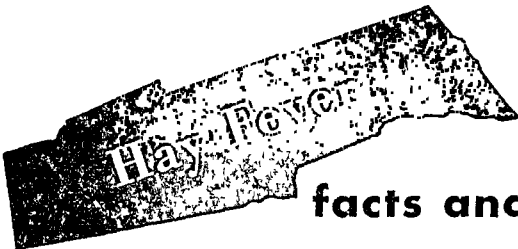

Pediforme shoes are prepared through experienced craftsmen to make the necessary adjustments as prescribed by the orthopedic surgeon or physician in these cases.

With purchases restricted it is readily apparent that substantial shoes, capable of reconstruction or easy adjustment, should be prescribed. For all practical purposes, Pediforme footwear may well be considered in shoe therapy.

The ORIGINAL ENTERIC-COATED TABLET  
OF THEOBROMINE SODIUM ACETATE

*to control frequency and severity of  
attacks in* **CARDIOVASCULAR AND  
RENAL DISEASES** *and to prevent EDEMA*

Clinical experience and studies have proven the value of Theobromine Sodium Acetate in certain Cardiovascular and Renal Diseases. In Angina Pectoris, used adequately, it permits more work by the individual without developing precordial pain or distress. As one of the most effective Xanthine Vasodilators it helps increase the available blood supply to the heart and kidneys to increase the efficiency of these organs.

It has also been found an effective aid in treating and preventing Edema of Cardiac or Renal origin. The enteric coating (especially developed for Thesodate) permits larger doses without the drug's contact with the Gastric Mucosa.

AVAILABLE IN  
various potencies with  
or without Phenobarbitol.  
Literature on request.

# Restores Vaginal pH. Destroys the Pathogenic Flora

In vaginal leukorrhea, Floraquin provides destruction of the pathogenic organisms and promotes rehabilitation of the vaginal mucous membrane. Containing the non-toxic protozoacide, Diodoquin, together with lactose and dextrose, this product of Searle Research removes the causative factors of leukorrhea and restores normal vaginal physiology.

Floraquin brings about the establishment and maintenance of an acidity (pH 4.0) unfavorable to vaginal infections. Its lactose and dextrose provide the necessary substrate for the production of lactic acid, a condition which enhances destruction of pathogenic organisms and promotes normal flora—Doderlein's Bacillus.

*For Office Insufflation*—Floraquin Powder in bottles of 1 oz. and 8 oz.

*For Home Routine*—Floraquin Tablets in boxes of 24

# Why PENICILLIN-C.S.C.

Penicillin-C. S. C.—available as penicillin calcium as well as penicillin sodium—is packaged only in rubber-stoppered serum-type vials containing 100,000 Oxford Units. The vials are used in preference to sealed ampuls because they make for greater convenience in storing the solution and because they lessen the danger of contamination after the solution is made.

Only vials of 100,000 units are offered at present because experience designates them as the most advantageous size. If there IS a factor in therapy which may undermine or lessen the remarkable therapeutic efficacy of penicillin, it may be underdosage. Even if therapy

is instituted late in the course of the disease, penicillin in many instances will prove effective if adequately high dosage is used for the proper length of time.

In the conditions so far explored and reported, effective dosage in some instances will be less than 100,000 units per day; in many instances it may have to be several times this amount. Hence in a large percentage of cases the Penicillin-C.S.C. vial of 100,000 units will prove most advantageous.

The convenience of the vial will be readily appreciated. After removal of the tear-off portion of the aluminum seal, sterilize the exposed surface of the

For the usual concentration (5000 Oxford Units per cc) inject 20 cc. of physiologic salt solution into the vial in the usual aseptic procedure

Invert the vial and syringe (with needle in vial) and withdraw the amount of penicillin solution required for the first injection

Store vial with remainder of solution in refrigerator. Solution is ready for subsequent injections during the next 24 hours.

# IS SUPPLIED ONLY IN 100,000 OXFORD UNIT VIALS

rubber stopper in the customary manner, inject into the vial 20 cc of pyrogen-free, sterile physiologic salt solution, without removing the needle invert vial and withdraw as many cc of this 5000 units per cc solution for the injection that is to be made immediately, store the vial with its remaining solution in the refrigerator—it is ready for use when the next injection is to be made.

The concentration withdrawn from the vial is 5000 units per

cc. If a lower concentration is desired, modification is easily accomplished.

If you have not as yet received a copy of the "Penicillin-CSC Therapeutic Reference Table," showing dosages, modes of administration, and duration of treatment required in the various infections in which penicillin is indicated, write for a complimentary copy now. You will find it a valuable guide and a real aid in familiarizing yourself with penicillin therapy.

- 3 Ten years of comprehensive research.
- 4 Extensive bibliographic background.
- 5 Ertron alone—and no other product—contains electrically activated, vaporized ergosterol (Whittier Process).

## Ertronize the Arthritic

**TO ERTRONIZE**—Employ ERTRON\* in adequate dosage over a sufficiently long period to produce beneficial results. Gradually increase the dosage to the toleration level. Maintain this dosage until maximum improvement occurs.

Supplied in bottles of 100 and 500 capsules.

**ETHICALLY PROMOTED**

\*Reg. U. S. Pat. Off.

For the physician who wishes to supplement the routine oral administration of ERTRON by parenteral injections, ERTRON Parenteral

is available in packages of six 1 cc. ampules. Each ampule contains 500,000 U.S.P. units of electrically activated vaporized ergosterol (Whittier Process).

# ESTIVIN

Assures

Prompt

Relief

from

*Hay  
Fever*

The prompt action and effectiveness of ESTIVIN enables the hay fever patient in most cases to pursue a normal mode of life during the dreaded "pollen months".

By exerting a soothing effect upon the irritated and congested membranes of the conjunctiva and nose, ESTIVIN produces welcome relief from the ocular and nasal symptoms.

One drop in each eye two or three times daily is generally sufficient to keep the average patient comfortable during the entire hay fever season. In more severe cases, additional applications whenever the symptoms recommence will keep such patients relieved throughout the day.

PLEASANT TO TAKE

**BULK...**

**WITHOUT "BLOAT"**

*A Natural Stimulus to Peristalsis*

**BASSORAN**

Brand of Sterculia Gum and Magnesium Trisilicate

**L**ow residue diets and the inactivity of convalescence predispose toward constipation

For such patients, Bassoran, taken with sufficient water, provides soft, non-irritating bulk—thereby encouraging the intestinal musculature to respond naturally and helping to promote easy evacuation

Bassoran is pleasant to take. It is also well tolerated—does not cause a feeling of fullness or "bloating" in stomach or bowel.

A distinctive combination of bulk-producing sterculia gum (87%) with antacid, adsorptive magnesium trisilicate (8.7%). For more obstinate cases, **BASSORAN WITH CASCARA** contains 72 minims F.E. cascara sagrada per ounce. Patients should be cautioned to use Bassoran with Cascara only as directed

Both types of Bassoran are available at prescription pharmacies in 7-oz and 25-oz bottles.

# IN IMPAIRED FAT DIGESTION

Degalol, the original chemically pure deoxycholic acid, is the constituent of human bile which is chiefly concerned with the emulsification of ingested fats.

When bile secretion is deficient, or totally lacking as in biliary fistula, the administration of Degalol assures not only digestion and

absorption of food fats but also of the fat-soluble vitamins A, D, E, and K.

When fatty foods prove intolerable in the absence of cholecystic pathology, Degalol usually relieves the postprandial distress and permits of liberalization of the diet.

Supplied in boxes of 100 1½ grain tablets.

Riedel - de Haen, Inc., New York 13, N. Y.

## Editorial

### Continuous Medical Education, II

The matter of continuous medical education in this nation was discussed editorially in this JOURNAL in the issue of July 15, 1944. It seems likely that the present policy of the armed forces, if continued, will result in an annual deficit of some 2,000 doctors. The House of Delegates of the A M A at its 1944 meeting

on the recommendation of the Council on Medical Education and Hospitals of the American Medical Association passed the following resolution at its opening session, June 12

students will inevitably result in an overall shortage of qualified physicians, with imminent danger to the health and well being of our citizens therefore be it

*Resolved, that it is imperative that immediate action be taken by the President or the Congress of the United States to correct the current drastic regulations, which result in a restriction of the number of students qualified to enter the courses of medical instruction in approved medical schools'*

This resolution was sent to the President, the Secretaries of War and the Navy, the Selective

Service System, and all members of the House and Senate Military Affairs committees

The latest measure still further jeopardizing medical education and medical care was the passage of the Army appropriation bill by Congress June 21. This bill includes the following provision

Provided that no appropriation contained in this Act shall be available for any expense incident to education of persons in medicine (including veterinary) or dentistry if any expense on account of this education in such subjects was not being defrayed out of appropriations for the military establishment for the fiscal year 1944 prior to June 7, 1944

This provision would seem to eliminate from 1946 entering medical classes the 28 per cent of places contracted for by the Army. Even if the Navy increases its quota from 25 per cent to 31 per cent, schools will be obliged to obtain 69 per cent of their students from women and physically disqualified males. Nothing even approaching this number of qualified civilian students is available. Classes will probably be half filled in the country at large.

So serious does this situation appear to be that all physicians must take immediate cognizance of it. The J A M A<sup>1</sup> says editorially

<sup>1</sup> J A M A 125 708 (July 8) 1944

"Should an adjustment not be made to correct the present alarming situation, a tremendous reduction of graduates after the war will ensue. Although schools will continue the accelerated program, they will admit classes only once annually instead of every nine months. This of itself will reduce the number of graduates from the present annual average of 7,000 to 5,000. If classes can be only half filled, this number will be reduced to 2,500 graduates per year. Since 3,300 to 3,500 physicians die each year, there will result an annual and cumulative deficit of 2,000 doctors a year.

"Still further reductions in graduates and permanent damage to the 'plant' of medical education will result from some schools being forced to close their doors because of drastically curtailed enrollments. An unknown number of war casualties among medical officers will also reduce the supply of physicians.

"These reductions in medical graduates will occur in the face of new and increased demands for medical services, mainly from the civilian population, the standing army and navy, the Veterans Administration and the liberated countries of Europe.

"Full support should be forthcoming from the medical profession for the Miller bill (*H.R. 5128*), with modifications, which reads:

"Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That Section 5 of the Selective Training and Service Act of 1940, as amended, is amended by inserting at the end thereof a new subsection reading as follows:

"(n) There shall be deferred from training and service under this Act in the land and naval forces of the United States, as necessary to the maintenance of the national health, safety and interest, in each calendar year not less than 6,000 medical students and not less than 4,000 dental students. As used in this subsection the term "medical or dental student" means (1) a person who is enrolled in, and who is pursuing a course of instruction prescribed for the degree of doctor of medicine at an accredited medical college; and a person who is enrolled in, and who is pursuing a course of instruction prescribed for the degree of doctor of dentistry at an accredited dental college; or (2) a person who is pursuing a regular course of instruction at an accredited college or university

(satisfactory completion of which will make such person eligible for enrollment in an accredited medical or dental college) with the bona fide intention of entering an accredited medical or dental college and pursuing and completing the course of instruction prescribed for the degree of doctor of medicine or for the degree of doctor of dentistry.'

"Protests against the blind disregard for medical care in the future should be addressed to the Senate (Senator Robert R. Reynolds, chairman) and House (Representative Andrew J. May, chairman) Committees on Military Affairs, the Senate Committee on Education and Labor (Senator Elbert D. Thomas, chairman), and the House Committee on Education (Representative Graham A. Barden, chairman). Every state medical society, medical school, and medical scientific society should express itself in no uncertain terms on these developments."

We take this second opportunity to bring this highly important matter to the attention of our readers and the appropriate committees of the Medical Society of the State of New York. Delay on a matter of such importance to the health and welfare of the nation may be disastrous indeed. All readers are urged to register their individual protests as called for by the A.M.A., without loss of time, to the Senate and House Committees on Military Affairs, the Senate Committee on Education and Labor, and the House Committee on Education.

The seriousness of interruption to the program of continuous medical education cannot be overestimated. Such legislation as may be necessary to resolve the present impasse between the Army and Navy and the Selective Service System is hereby called for in the interest of the maintenance of the national health without which industrial production and the provision of the sinews of war would undoubtedly be drastically curtailed.

## Politics Again?

Now, in addition to *S. 1161*, we find *H.R. 4371*, introduced in the House of Representatives in March, 1944. We hope most of our membership is by now familiar with the questionable medical and hospitalization provisions of the Wagner Bill. We are indebted to *Industrial Medicine*<sup>1</sup> for calling attention editorially to *H.R. 4371*, which

supersedes *H.R. 2800*. Says *Industrial Medicine*:

This is a bill that ought to have a lot of publicity, principally because its progress and that of *H.R. 2800*, which it supersedes, have been directed so secretly, and so suddenly. These bills express the Perkins-inspired effort to have the Department of Labor take over the industrial hygiene activities of the various states. Hearings on the original bill

were held on five days in June, 1943, and no one connected with the U S Public Health Service or any state department of health knew about these hearings until after they had been concluded. *H R 4371*, now pending, aims to provide for the Labor Department to cooperate with "state agencies administering labor laws in establishing and maintaining safe and proper working conditions in industry and in the preparation, promulgation, and enforcement of regulations to control industrial health hazards." It would authorize \$5,000,000 a year to be allotted, by the Secretary of Labor, "for use by cooperating state agencies administering labor laws on the basis of (1) the population, (2) the number of wage earners, (3) the special safety and health problems in industry, (4) the number of workers afforded protection by the state laws and the cost of proper and efficient administration of such laws, and (5) the financial needs of the respective states." The money so allotted to any state "shall be extended solely in carrying out the purposes specified and in accordance with rules and regulations prescribed by the Secretary and the plans jointly developed by the agency administering the labor laws of such state and the Division of Labor Standards and approved by the Secretary of Labor. In the operation of such plans the available services and facilities of public health authorities in the field of industrial hygiene shall be utilized." The Secretary is to have a "Safety Advisory Commission . . . hereby authorized and directed to recommend . . . reasonable standards, methods, and procedures for establishing safe working conditions in industry with a view to encouraging more effective control of hazardous conditions by the several states." There will be the usual "such employees," appointed by the Secretary, and the usual fixing of their compensation. An additional quarter million per year for "all necessary expenses" in administration is to be provided. The [quoted] lines indicate the important additions to *H R 2800* which appear in *H R 4371*.

Referring to the statements in quotation marks above, *Industrial Medicine* asks

Are these "weasel words?" Does the "shall be" mean that the "available services" are to be asked, or to be ordered? Or will the next step be to insure the desired state cooperation by holding out the bait of larger allocations from the five million to those states which will transfer their industrial hygiene activities from the state health to the state labor departments. In some such way the "available services and facilities" could be got around and wouldn't be needed. No one familiar in any respect with current bureaucratic interpretations of Acts of Congress, nor past bureaucratic pressures on state governments through allocations of Congressionally appropriated funds, can fail to foresee the conflicts of authority, the confusions and duplications, and the insidious pressures that are inevitable here. But here the possibilities are more or less evident. What else lurks in the disguised intentions of the smooth way in which the "enforcement of regulations to control industrial health

hazards" is woven into the text of the bill? Or in the powers delegated to the "Safety Advisory Commission," which would authorize it to confuse and interfere with health regulations and procedures already put into satisfactory effect by the public health authorities? And the carefully detailed basis of the allotments by the Secretary, to the "cooperating state agencies administering labor laws?" Why not the "cooperating state agencies administering health laws?" But that, of course, is a foolish question!

There is no doubt about the political education which is being afforded the profession of medicine, perhaps as a postgraduate study, by the authors of much current legislation. Much of it concerning medicine unfortunately simply serves to arouse suspicion, distrust, and lack of confidence, provokes doubt and skepticism and a presumption of bad faith, is looked at askance by physicians, and scrutinized with the microscope, as it should be, for evidence of duplicity, skulduggery, rascality, and all manner of naughtiness.

The unctuous rhetoric that oiled the arguments of the Labor Department for this bill, says *Industrial Medicine*, revolved around the lost time and cost of industrial accidents and the need for accident control. The accident situation was likewise the burden of the other testimony heard by the Committee.

When it became noised abroad that the almost *ex parte* hearings on the first bill had been held, a salvo of cogent arguments against it was prepared for the information of the Congressmen. These arguments are implicit in the circumstances.

1 Industrial hygiene is a health matter, not a labor matter.

2 Industrial hygiene activities are now being handled, and excellently handled, by the Federal and state public health officers, through their Divisions of Industrial Hygiene, and their sanitary, engineering, laboratory, nutrition, and other public health facilities.

3 The present effort to extend the scope of the Labor Department's authority to the control of industrial health hazards and to "special safety and health problems in industry," in so far as health and health hazards are concerned, disregards the obvious fact that such extension would duplicate existing facilities. This duplication is completely unnecessary—so patently unnecessary as to label the efforts to bring it about bureaucratic and political in the worst sense in which these terms are critically employed, to say nothing of the fact that the proposal involves a wholly needless expenditure of taxpayers' money.

4 Health departments have the ability to carry on health and hygiene services impartially. This is inherent in their professional status, for this status not only demands the ability but also imposes the duty to be impartial. No physician, no engineer, will risk his reputation by being anything but im-

partial. This, however, cannot be said of those whose tenure of position depends on the good will of pressure groups, graded preferences, and partialities. . . .

From the standpoint of all persons interested in health, and this includes everyone—physicians, hygienists, employers, and employees, whether they belong to a union or not—this bill should be defeated. This for the reasons above mentioned and the further reason that it is not honest. If it were honest, its avowed purpose would be to improve health, and the five million would go to the state and Federal health agencies instead of only to "cooperating state agencies administering labor laws." The existing health agencies could use more money. Their combined budgets for the best year they ever had weren't half of five million. They know how to spend money wisely and effectively for health purposes, and they have done and are doing a fine job. They are experts, qualified by profession and by experience, and they do not need nonmedical competition. Instead, they need help. They could use more appropriations and more personnel. A little of both distributed among them would enable them to add more to what they are now doing for health than many times as much would enable the Department of Labor to do in toto in ten times the same period.

With this opinion we are in complete agreement. Overreaching by governmental

departments must also be discouraged. As *Industrial Medicine* concludes:

We have no idea regarding what the Department of Labor might accomplish in safety, if it confined its overreaching to that alone. But we do have a good picture of what it cannot accomplish in industrial health and hygiene. That picture includes everything except more offices, more power, more pressure on the states to "cooperate," and more confusion. Meanwhile, how is anybody's health going to be improved? Health cannot be legislated into a plan, any more than disease can be "collectively bargained" out of it. . . .

Education plays an important role in accident control, and if the Secretary of Labor and her advisers were as primarily interested in safety as they would have us assume, the facilities of her department would be forcibly brought to bear on the one safety measure that will really reduce accidents: "safety education."

Here, we think, is a legitimate and proper activity for the Federal Department of Labor and one which would certainly promote increased production and have the enthusiastic cooperation of physicians.

<sup>1</sup> Vol. 13, No. 5, May, 1944, p. 406 *et seq.*

<sup>2</sup> Committee on Labor, whence it emerged with majority approval; but a minority report by Rep. A. L. Miller (Nebraska) caused it to be sent to the Committee on Rules.

## Pelvioradiography

Prophylactic measures do not always consist of specific inoculations, specific chemotherapy, or isolation procedures. It is generally acknowledged that more accurate estimation of the capacity of the obstetric pelvis has contributed much to the decrease in maternal and fetal morbidity and mortality of the last decade. Obstetricians now realize that external and internal pelvimetry suffer from limitations which not infrequently fail to give a true picture of the architecture of the pelvis. The superiority of roentgen measurements over clinical calculations of abnormal pelvis has been amply demonstrated.<sup>1,2</sup>

Recent studies of pelvioradiography have only served to confirm and extend its usefulness in obstetric prophylaxis and treatment.<sup>3</sup> Two hundred and eighty cases of anticipated dystocia were investigated by a meticulous technic fully described in the paper referred to above.<sup>3</sup> The fetal head is always simultaneously studied in relation to the size of the pelvic outlet and its probable ability to effect safe passage. While the ample pelvis could be diagnosed clinically almost as well as by x-ray studies, a marked discrepancy was revealed when the contracted pelvis was subjected to both procedures. Only 59 per cent of contracted pelvises were correctly

suspected by clinical pelvimetry, while by pelvioradiography the percentage of accurate diagnoses was 84 per cent. Needless to say, to arrive at a true obstetric diagnosis the obstetrician should blend the knowledge obtained from both clinical and x-ray sources. Cesarean operation was indicated with great accuracy if pelvioradiography revealed a contracted pelvis, yet that this method was conservative was demonstrated by the fact that only 40 per cent of this dystocia series was subjected to operation.

Pelvioradiography has already played a role in reducing the number of stillbirths and in decreasing maternal morbidity. It should become an important feature of the obstetric armamentarium in the management of dystocia. Such procedures are a valuable prophylactic measure in saving and conserving lives and preventing illness. They are of the same order as the prophylactic measures of vaccination and inoculation against contagious diseases.

# CLINICAL EXPERIENCE WITH PENICILLIN\*

DONALD G. ANDERSON, M.D., Boston

IT IS not quite four years now since an interest in penicillin was first awakened in this country. In the brief space of time that has since elapsed, outstanding progress has been made in solving the many complex problems involved in the large-scale production of penicillin. It was only two years ago that penicillin first became available in sufficient quantity to permit even the most limited clinical investigation. Today penicillin is being supplied to hospitals in every part of the country.

Last summer the Committee on Chemotherapeutics and Other Agents of the National Research Council, under the Chairmanship of Dr. Chester S. Keefer, reported on the use of penicillin in 500 cases.<sup>1</sup> The results of treatment in several thousand cases are now available, but even this experience can be regarded as only a beginning, and the next year or two will undoubtedly see a tremendous increase in our knowledge of both the possibilities and the limitations of penicillin therapy.

Since many of the problems involved in the use of penicillin arise from its peculiar pharmacologic properties, I should like to review briefly the important work done by Dr. Rammelkamp and Dr. Keefer on the absorption, distribution, and excretion of penicillin.<sup>2</sup> I should perhaps first define the Oxford unit, since it will be referred to frequently in the discussion that follows. Chemical assay of penicillin is not yet possible, and the drug must, therefore, be measured in terms of its antibacterial activity. The Oxford unit is an arbitrary standard, and by definition is "that amount of penicillin which, when dissolved in 50 cc. of meat extract broth, just completely inhibits the growth of the test strain of *Staphylococcus aureus*."

Penicillin is rapidly inactivated by the hydrochloric acid of the gastric juice, and following oral administration very little, if any, of the drug appears in the blood. Absorption from the rectum is also poor. When penicillin is introduced directly into the duodenum, slightly better absorption occurs, but efforts to treat patients by this route have not been successful.

It is apparent at once, then, that adequate absorption of penicillin cannot be obtained by enteral administration.

Following intravenous injection, the concentration of penicillin in the blood reaches an immediate peak and then rapidly falls. The persistence of penicillin in the blood depends somewhat on the amount injected, but even with fairly large doses very little of the drug can be detected in the blood after two hours.

The reason for this rapid disappearance of penicillin from the blood becomes clear when one studies the excretion of penicillin by the kidney. In patients with normal renal function, the drug appears in the urine within two to three minutes after injection, and at the end of one hour an average of 58 per cent of the amount injected will be excreted by the kidney. In patients with impaired renal function, excretion is delayed and is not so complete. In such cases, fairly high blood levels may be maintained for relatively long periods of time.

Records have been kept of the blood level curves obtained after the administration of 10,000 units of penicillin by three different routes. The typical curve that follows intravenous injection we have already noted. After intramuscular injection, the concentration in the blood rises somewhat more slowly and reaches a lower peak. The peak level, however, is sustained for a slightly longer period of time than after intravenous injection.

Subcutaneous injection produces a low concentration in the blood. The subcutaneous injection of penicillin is often painful, and the usefulness of this route appears to be limited.

From these studies, it is clear that if effective amounts of penicillin are to be maintained in the body throughout treatment, the drug must be given at frequent intervals by intravenous or intramuscular injection. The use of a continuous intravenous drip is also a satisfactory method of administration and probably permits the most efficient utilization of the drug. When the drip is properly regulated, it is possible to maintain a more or less constant level of penicillin in the blood at all times. This advantage is somewhat offset, however, by the increased inconvenience that it causes both the patient and those taking care of him.

Studies on the distribution of penicillin in the body after intramuscular or intravenous injection revealed that the drug does not pass into the cerebrospinal fluid, and that none, or at the most an insignificant amount, passes into the

\*Read at the Annual Meeting of the Medical Society of the State of New York, New York City, May 9, 1944.

search and Development from supplies assigned by the Committee on Medical Research for clinical investigations recommended by the Committee on Chemotherapeutics and Other Agents of the National Research Council.

various serous spaces of the body. It follows, then, when one is treating infections of the meninges, of the body cavities, or of the joints, that the introduction of penicillin locally into the infected cavity is desirable. Since absorption from these sites is slow, penicillin need be introduced only once or twice daily.

In vitro tests of bacterial susceptibility have been of great value in guiding clinical studies.<sup>3</sup> The following list includes the more important pathogens that have been found to be sensitive to the action of penicillin:

Gonococcus	Streptococcus viridans
Meningococcus	(most strains)
Hemolytic streptococcus	Clostridium tetani
Pneumococcus	Clostridium welchii
Staphylococcus	Corynebacterium diphtheriae
Nonhemolytic streptococci (most strains)	Actinomyces bovis
	Treponema pallidum

Except for the gonococcus and the meningococcus, the susceptible organisms are all gram-positive bacteria. These various species differ significantly in their relative sensitivity to the action of penicillin. They are listed here in the general order of their susceptibility, those at the top of the list being inhibited by much smaller amounts of penicillin than those at the bottom. It is also well recognized that different strains of the same species may exhibit marked differences in susceptibility.

The following list includes some of the more important pathogens that have been found to be insensitive to the action of penicillin. It can be seen that penicillin has no effect against the whole group of gram-negative bacilli.

Enterococcus	Pseudomonas aeruginosa
Escherichia coli	
Bacillus typhosus	Friedländer's bacillus
Bacillus paratyphosus	Brucella group
Bacillus dysenteriae	Mycobacterium tuberculosis
Haemophilus influenzae	
Haemophilus pertussis	Pasteurella pestis
Haemophilus ducreyi	Pasteurella tularensis
Vibrio cholerae	Yeasts
Bacillus proteus	Molds

It might be added that preliminary studies have shown that penicillin has no action against the viruses.

Susceptible bacteria have been made penicillin-fast in the test tube by adapting them to increasing concentrations of the drug, and the development of drug-fastness during the treatment of clinical infections has been observed on several occasions.<sup>4</sup>

Regarding the mode of action of penicillin in human infections, it is now quite clear that its

action is bacteriostatic rather than bactericidal. In patients who eventually recover, blood cultures and cultures of the local lesions often remain positive for several days after the beginning of therapy, and relapses have been frequently observed when penicillin has been discontinued too soon after the first signs of improvement have appeared or after the first negative cultures have been obtained.

From this fact—that the action of penicillin is bacteriostatic rather than bactericidal—it follows that the duration of treatment is an important consideration in the use of penicillin, and also that the general condition of the patient and the state of his normal defense mechanisms are important factors in determining the outcome of treatment. It has been conclusively shown that even massive doses of penicillin will rarely save a patient who is moribund.

Penicillin is not inhibited by para-aminobenzoic acid, pus, peptones, or the breakdown products of tissue autolysis.

I should like to consider now some of the results that have been obtained with penicillin therapy. As a general rule, we use a solution containing 5,000 units of penicillin per cc. of normal saline and administer appropriate amounts of this solution either intravenously or intramuscularly at three-hour intervals throughout the day and night. For most purposes, the intramuscular route is the more convenient; and when multiple injections are being given, the intravenous route does not seem to offer any particular advantages. In treating seriously ill patients we frequently employ a continuous intravenous drip until definite signs of improvement have appeared, after which time treatment is continued by the intramuscular route. When penicillin is given by a constant intravenous drip, the dosage varies from 5,000 to 20,000 units per hour, depending on the circumstances.

A word about dosage in general. The optimum dosage for most conditions has not yet been determined. Of necessity, efforts to date have been directed toward discovering the minimal effective dose rather than the optimum dose. However, it would appear that for adults a dosage of 15,000 units every three hours is adequate in almost all conditions. Occasionally, in fulminating infections, larger doses may be indicated for a few days until the disease has been brought under control.

The results of penicillin therapy in sulfonamide-resistant gonococcal infections have been widely publicized. The pioneer work in this field was done by Dr. Mahoney, of the United States Public Health Service at the Marine Hospital on Staten Island.<sup>5</sup> Mahoney demonstrated that in males prompt and permanent cure results in 98

to 99 per cent of cases when a total dosage of about 100,000 units is given over a period of twelve to fifteen hours. Many cases respond to even smaller doses. Dr Alfred Cohn of New York has recently demonstrated that equally good results can be obtained in female patients.<sup>6</sup>

Experience with the use of penicillin in meningococcal infections has been limited. In view of the success and simplicity of sulfonamide therapy, it seems unlikely that penicillin will play an important role in the management of meningococcal meningitis except as an adjuvant measure in particularly severe cases.

A considerable group of patients with pneumococcal infections have now been treated with penicillin. Much of this work has been done by Dr Tillett in New York City.<sup>7</sup> In pneumococcal pneumonia, the mortality rate has been in the vicinity of 6 per cent, a result which indicates that penicillin is an effective agent in the treatment of this disease. Whether it will prove to be significantly more effective than the sulfonamides, of course, cannot be determined until many more cases have been studied. The optimum schedule of treatment has not been settled, but it appears from Tillett's work that a total dosage of 200,000 to 300,000 units, given over a period of three or four days, will be adequate for most cases, although recovery has followed the use of even smaller amounts.

*Case 1*—Our patient was a man of 60 whose illness was of more than average severity despite the fact that the blood culture was sterile. He received a total of 200,000 units over a period of seventy-two hours and made a very satisfactory recovery.

Several cases of pneumococcal empyema have cleared without surgical drainage following the daily instillation of 25,000 units of penicillin directly into the empyema cavity over a period of three or four days. Occasionally sterile pus will continue to form, and in such instances thoracotomy usually becomes necessary. In other cases, loculation of the fluid prevents the diffusion of penicillin throughout the cavity. In such cases, surgical drainage must also be resorted to.

It was, of course, hoped that penicillin would significantly improve the outlook in pneumococcal meningitis. Approximately two hundred patients have now been treated, with only 45 per cent recovering.

Most of these patients were treated with penicillin alone. It is possible that the use of penicillin in combination with intensive sulfonamide and serum therapy will give better results. But experience has already shown that even such combined therapy will frequently fail.

*Case 2*—One of our patients was a 79-year-old man in whom treatment was begun after he had

been ill for eighteen hours. The primary focus was never established. Both blood and spinal fluid were heavily infected with *Pneumococcus*, type 12. Large doses of penicillin were given both intravenously and intrathecally, with the result that after twenty-four hours striking improvement had occurred.

On the third day a complete spinal subarachnoid block developed and the intrathecal administration of penicillin was discontinued. On the fifth day there was a sudden rise in temperature, and the patient lapsed into coma. Cisternal tap revealed fluid that was still heavily infected with pneumococci. Penicillin was then administered intrathecally by way of the cisterna magna until the block disappeared seven days later. The patient eventually made a complete recovery. While still receiving large doses of penicillin, he developed a severe bilateral parotitis for which x-ray therapy was given with good result. Culture of the pus from Stensen's duct revealed a pure growth of *Staph aureus* which was found to be highly resistant to the action of penicillin.

We have recently treated a patient with pneumococcus meningitis who required intrathecal injections of penicillin twice a day for nine weeks before his spinal fluid was permanently sterilized. Other workers have reported similar experiences.

Several patients with pneumococcal endocarditis have now been treated with penicillin. Most of these patients have died, but a few, in whom there was no doubt as to the diagnosis, appear to have recovered. One patient whom we treated has remained well now for more than a year.

The action of penicillin in subacute bacterial endocarditis caused by *Streptococcus viridans* cannot be satisfactorily evaluated at this time. Early experiences were uniformly discouraging,<sup>1</sup> and further study of the problem was postponed until the supply of penicillin became more plentiful. Recent experiences with the use of larger doses of the drug have given immediate results that are encouraging in some, but in by no means all cases of this disease. It seems clear that this problem will require prolonged study before any definite conclusions can be established.

The hemolytic streptococcal infections that have been treated are too few in number and have included too diverse a group of infections to permit statistical evaluation. Results in individual cases indicate that penicillin is an effective agent against this organism.

Penicillin therapy of experimental Welch bacillus infections in animals has been very promising. Only a few human infections have been treated with penicillin, but in some of these cases its use in large doses has appeared to be the chief factor in recovery. It is clear, however, that the thorough removal of necrotic tissue and the use of antitoxin cannot be omitted.

The clear-cut action of penicillin in early syphilis has been reported by Mahoney.<sup>8</sup> It is accepted that no final estimate of the value of penicillin therapy in syphilis can be made until a long period of observation has elapsed.

Interest in the clinical use of penicillin has, of course, centered on its effectiveness in staphylococcal infections. More than 550 patients with staphylococcal bacteremia have been treated with penicillin. Seventy-one per cent of these patients have recovered, giving a mortality rate of 29 per cent. It will be recalled that the overall mortality rate in untreated staphylococcal bacteremia was 85 per cent, and that with sulfonamide therapy the mortality rate remained in excess of 60 per cent. In nearly a thousand cases of serious staphylococcal infections without bacteremia, recovery or improvement has taken place in 81 per cent.

The results of treatment in these 1,500 odd cases leave no doubt that penicillin is a potent agent in the therapy of staphylococcal infections, although there still remains a substantial group in which, for a variety of reasons, therapy is not successful.

In contrast to the small doses and short periods of treatment which are usually adequate in gonococcal, meningococcal, pneumococcal, and hemolytic streptococcal infections, staphylococcal infections have been found to require prolonged and intensive therapy.

*Case 3.*—A 19-year-old girl had a staphylococcal pneumonia with bacteremia and had developed multiple subcutaneous abscesses and a suppurative arthritis of the ankle while receiving sulfamerazine. Treatment with penicillin was begun on the fifth day of her disease. She received a total of 3,500,000 units over the space of twenty-three days, and eventually made a complete recovery. We were especially gratified with the complete resolution of the arthritis without surgical drainage. At the beginning of treatment, 8 cc. of thick pus, which showed a heavy growth of *Staph. aureus*, was aspirated from the joint. Daily aspirations followed by the injection of penicillin were continued for eight days. The joint fluid became sterile, and there was a complete return of function to the ankle. Cultures of the blood and of the joint fluid, however, did not become sterile until after several days of treatment.

*Case 4.*—A 2-year-old child had been severely ill with staphylococcal pneumonia with bacteremia for four days before penicillin was started. Large doses of the sulfonamides were given without improvement. Following the institution of penicillin therapy, defervescence was gradual, but recovery was finally complete. It has been remarked by many observers that in severe staphylococcal infections treated with penicillin, marked subjective and objective improvement in the patient's general condition is very apt to occur before there has been any striking reduction in the temperature.

Penicillin has proved to be a very useful agent in the management of chronic osteomyelitis. Almost all patients who have been treated have been distinctly benefited. In about 75 per cent, all drainage has disappeared and the sinuses have healed. Unfortunately, many have relapsed within a few months. It seems clear that those patients in whom all sequestra are removed will do better than those in whom this procedure is not carried out.

One of the most striking properties of penicillin has been its lack of significant toxicity for the host. Some reactions have been encountered, but none of them was serious. No toxic effects on the liver, kidneys, or blood-forming organs have been observed during the course of penicillin therapy. This lack of toxicity is even more striking when one considers that the preparations available today contain a high percentage of impurities. It might be best, however, to reserve final judgment regarding the harmlessness of penicillin until many more cases have been treated. As yet there is no evidence that patients will develop a sensitivity to penicillin, and at present there are no known contraindications to its use.

In summary, we can say that clinical experience has shown penicillin to be an effective therapeutic agent against a variety of micro-organisms. In many cases the use of penicillin alone will insure recovery from serious infection. In another large group of cases, penicillin should more properly be considered as a valuable adjunct to other established forms of treatment, particularly surgery.

All aspects of penicillin therapy require further study. This is particularly true with regard to the possibilities contained in prophylactic use of penicillin and with regard to the use of penicillin in combination with the sulfonamides.

But while many problems remain to be explored, the experience of the past two years has definitely established the value of penicillin as a therapeutic agent and has also pointed the way for the development of sound principles of penicillin therapy.

# OTOLARYNGOLOGIC PROBLEMS OF AVIATION

PAGE NORTHINGTON, Capt., (MC), USNR, New York City

THE practical interest of the specialist in the diseases of the ear, nose, and throat in aviation medicine has grown with the increasing volume of personnel who fly. In a brief span of years we have come to count aviation personnel in millions instead of in hundreds and thousands. It is not only the pilots but also other members of the airplane crew and the passengers who are exposed to conditions brought about by flying. Although the flight surgeons and medical examiners perform the examinations of the pilots, they see relatively few of the civilian flying personnel who seek treatment or advice either on the occasion of an anticipated flight or because of some ailment following a flight.

To be able to give useful advice to this personnel who consult physicians requires some familiarity with the medical problems encountered in aviation.

## Aerial Equilibration

The flyer when he has lost contact with the ground is no longer subject to the uniform forces of gravity and the fixed points of reference that had enabled him to maintain his equilibrium so easily. He may pilot his airplane through any maneuver without experiencing disturbance of equilibrium so long as he has control of and is aware of the attitude of the airplane. For example, if the pilot flies his plane through the maneuver called a spin, and intentionally pulls out for horizontal flight, there is no evidence of any disturbance of his equilibrium, but as often happens, if the flyer without much experience pulls out of a spin and is unable to control the attitude of the plane, allowing it to drop off into another spin, there is a disturbance of his equilibrium.

In the organization of the functional nervous system, equilibrium is dependent on sensations mediated through the visual, and vestibular and the sensory spinal nervous systems. When any two of these component systems are functionally intact there is no disturbance of equilibrium, or it is so slight as not to interfere with the ability of the pilot to keep the right end of his plane uppermost and to get from place to place. On the other hand, if there is impaired function of any two of these sensory systems there is a manifest disturbance of equilibrium. The common example of this is the disturbance of equilibrium noted when a person who has a disease of the

posterior spinal column attempts to walk in the dark. Such a person has been deprived both of visual aid and of the impulses arising from the skin, muscle, joints, and tendons.

We are familiar with the history of the introduction of tests of the vestibular function in the aviation physical examination, adopted in the first war. The Bárány chair test for after-rotary nystagmus, vertigo, and post-pounding was new, and many claims of its value in the selection of applicants for pilot training have not been borne out by experience. This is not the fault of the vestibular test but of false interpretation of the results. To qualify the applicant had to come within certain arbitrary limits for after-rotary nystagmus time. Experience with aviation personnel, as well as in clinical practice, has demonstrated that the reactions induced by the rotation test have considerable quantitative variations in normal persons. The Bárány chair test never has been required in the examination of civilian flying personnel and at the present time is used only on the initial examination in the Navy. The applicants for flight training are usually healthy young men with good medical histories. Unless there is something brought out in the history or on the comprehensive physical examination to suggest further investigation of the vestibular function, the only tests used are the Romberg test and the test that involves standing on one foot with the eyes closed. If an applicant's performance on these tests is unsatisfactory a more searching examination should be made to learn the cause of his disturbance of equilibrium.

Applicants for flight training who have symptoms of a vestibular disorder in the history or on examination or who have ear disease that is likely to produce a vestibular disturbance are not acceptable.

A foreign stunt pilot, whose acrobatics were the most spectacular that I have ever witnessed, was found on examination to have a postauricular fistula following a simple mastoidectomy. He would swoop down in an outside loop until his head was within three feet of the ground. It would seem hazardous for him to fly because if his chin strap should be loosened, his inner ear might be exposed to a blast of cold air, with disastrous consequences. Patients with a radical mastoidectomy cavity have had dizziness caused by the excitation of the exposed vestibular end organ from no greater stimulus than the air from an electric fan. Applicants with a dry

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, May 6, 1943.

perforation of the ear drum will meet the physical standards only for the grade of private pilot. The impossibility, in many cases of dry perforations of the ear drum with cholesteatoma, to make the diagnosis until the patient has been seized with intense vertigo that causes uncontrollable disturbance of equilibrium would make it doubtful that such applicants should be acceptable for any type of license.

Airsickness, like seasickness, does not permit of a satisfactory explanation of its cause. There is considerable evidence, however, to support the opinion that those who suffer from airsickness are persons who do not have such stable nervous systems as those who have a high degree of immunity. Airsickness is relative to certain conditions, depending, as it does, both on the individual's susceptibility to the effects of motions and on the intensity of the sensory stimulation from the angular course taken by the airplane. It may be truthfully said that no one will invariably suffer from airsickness on airplane flights and also that no one has complete immunity to it. The supposition that susceptible individuals have hypersensitive vestibular end organs is not valid because it has been demonstrated that there is no parallel between the reactions to vestibular tests and the susceptibility to airsickness. It may be that those with considerable immunity to airsickness have a relatively greater degree of control, coordination, and even suppression of sensory stimuli in the higher centers of the nervous system. In addition to the psychic factors and the vestibular stimuli, there are to be reckoned with the visual, olfactory, and gastrointestinal stimuli.

Student aviators who experience airsickness are almost invariably those in the early acrobatic training stage. It is common experience that focusing the vision on some object other than the carrier that one is riding in will aid in maintaining equilibrium. Relying on this principle, Flaherty<sup>1</sup> used the following procedure on naval student aviators who complained of airsickness.

These students were instructed by him to carry out the following routine:

1. To adjust the seat to a high position in the plane so that visibility would be at the maximum. Each man was cautioned to be certain that full throw of the rudder paddles was possible after adjusting the seat to this high position.

2. To fasten the safety belt as firmly as possible. This was done in order that the proprioceptive sense would be at its best, as all seat movements would be felt in a firm but smooth manner.

3. To keep the eyes out of the cockpit at all times except for casual glances at the instruments. It was found that practically all stu-

dents had the tendency to "look" the controls through on maneuvers during instructions rather than to "follow" or "feel" the controls through, as they were instructed to do. In "looking" the controls through, their eyes were continually focused in the cockpit, and they had practically no idea of the position of the airplane in relation to the earth. Owing to this fact, it was found that nearly every student felt better when he was either soloing or flying the plane with the instructor present, for on these occasions he was forced to use his vision more in order to keep oriented. The fact that the students felt better while soloing also tends to disprove the often-made statement that airsickness is due to a fear reaction.

4. To pick out some point of reference a long way from the airplane. This is by far the most important instruction given to the student. In executing a loop, a point on the ground should be watched on the initial "nose-over," and after the top of the loop has been reached, a point on the horizon should be selected and the airplane brought down in alignment with this point, additional objects being selected as needed for points of reference. The same procedure was used in an Immelmann turn. In spins, points of reference on the ground should be followed at all times, and the eyes should never be fixed on the nose or the wings of the airplane. This is essential in doing precision spins; otherwise the student has little idea where to begin recovery in order to stop the spin at the desired point. In the performance of "wing-overs" he was advised to do the maneuver relative to a straight stretch of road, fence, line, or similar object whenever possible. It was found that most students who became airsick during this maneuver spent a great deal of time looking in the cockpit at the air-speed meter and the "needle and ball" indicator, thus literally flying mechanically by instruments and never using points of reference on the earth's surface. In snap rolls, a point on the horizon or a cloud bank could be taken as a point of reference. This point can be followed during the maneuver, and the student will know his position throughout the roll.

5. The same type of maneuver should never be tried over and over again because this tends to cause airsickness to a far greater extent than if the maneuvers are varied. The student should also wait a short interval between different acrobatics.

6. Never to attempt to land an airplane if he is extremely airsick. It is much safer to stay at a reasonable altitude until the airsickness has subsided.

Flaherty concluded that "airsickness can ordinarily be overcome when a student becomes

oriented in the air, as by using his eyes to pick up points of reference on the ground."

Relatively few student pilots have to discontinue their flying on account of airsickness, although many experience it in some stage of their training. It is not considered safe for a pilot to take drugs in the attempt to relieve himself of airsickness, but the doctor may use the same favorite prescription that he has given passengers for seasickness, and without expecting any more favorable results. Bromides and barbiturates have been used with indifferent success. Atropine in large doses is probably the most efficacious drug. Passengers who have planned a flight, especially if they suffer from airsickness, should avoid constipation and excesses in alcoholic beverages, and should have a good night's sleep before a trip.

### Auditory Acuity in Aviation

The faculty to hear well is useful to the aviator in many respects. Hearing defects may be responsible for propeller accidents which if not always fatal, are severe. Many flyers who have not had their attention directed to the revolving propeller have met with such accidents. This hazard is increased by impaired hearing because the slowly revolving propeller, when the motor is idling, makes little noise. Operations at night on aircraft carriers and to some extent in airfields in certain war areas are carried on without lights. When the airplanes are closely assembled the pilot may have to crawl along the deck in the dark to find his airplane in the midst of many idling motors, and an acute sense of hearing is of great assistance. In flight the pilot's detection of early signs of motor failure or of structural damage to the airplane has saved many from crashes.

The common use of radio in connection with almost all types of flying today requires that aviators have sufficient hearing to use their radios to the best advantage. Amplification of the message being received is not always possible, and, if it were, the static in the presence of interference would also be made louder. When the visibility is poor, flying is done largely on the radio beams. It is essential that the aviator have in his hearing no tone gaps that correspond with the frequency used on the beams.

### Case Reports

**Case 1**—An airline pilot was found on his routine physical examination to have a slight loss of hearing for the whispered voice. He was 32 years of age and had been flying for twelve years. During the first three years most of his flying had been in open cockpit airplanes.

The loss of hearing for the tones 4096 and 8191

TABLE 1—SOUND INTENSITIES IN DIFFERENT TYPES OF AIRCRAFT AND THOSE FROM OTHER FAMILIAR SOUND SOURCES<sup>1</sup>

Energy Units	Decibels	Examples
10,000 000 000 000	130	Airplane noise—pilot's head out in slip stream (threshold of painful sound)
1,000 000 000 000	120	Artillery gunfire
100 000 000 000	110	Airplane noise—open cockpit
10 000 000 000	100	Airplane noise—closed cockpit
1 000 000 000	90	Automobile horn
100 000 000	80	Airplane noise—soundproofed cabin
10 000 000	70	Stenographic room
1 000 000	60	Airplane noise—ultra modern soundproofed cabin
100 000	50	Ordinary conversation
10 000	40	Average residence
1 000	30	Slight rustling of leaves
100	20	Whisper
10	10	One's own heartbeat
1	0	Absolute stillness

was not considered disqualifying because the frequencies of the radio beams are between 200 and 400 kilocycles.

Although good hearing in an aviator is desirable, impairment of hearing may be one of the hazards incident to his occupation. The loss of considerable hearing in aviators is not very common, but it occurs at times as it does in others who work in the midst of loud noises. Otolologists have seen patients whose deafness was attributed to being exposed over a long period of time to loud noises and also some who were exposed to an abrupt, intense noise of short duration. Those aviators that develop deafness have a greater loss for the high pitch tones and a shortened bone conduction which is similar in type to the deafness found in any other workers who are exposed to noises of great intensity.

**Case 2**—A racing pilot, aged 28, was aware of a gross loss of hearing in both ears immediately after a race in which he had been a contestant in an open cockpit airplane. On examination five years later the drums appeared to be normal, and there was nothing in the history to indicate that his drums had been ruptured or that there had been an infection. He believed that there had been a slight improvement in his hearing since the time of the damage to his ears.

The audiogram showed a loss of hearing by air conduction of between 40 and 50 decibels in each ear for the tones 64, 128, 256, 512, and 1024, with comparable loss in bone conduction. There was complete loss of hearing for the upper tones.

The intense noises produced by the propeller, motor, and the slip stream that pilots were exposed to in the past have been greatly lessened by the cabin type of airplane and by soundproofing. The following table of sound intensities illustrates how effective soundproofing of aircraft has become.

Although soundproofing has to a great extent

TABLE 2.—COMPARATIVE VOLUMES OF THE GASTRO-INTESTINAL GASES AT VARIOUS ALTITUDES<sup>2</sup>

Altitude	Atmospheric Pressure	Gas Volume
0 feet	760 mm. Hg	1.0
8,000 feet	564 mm. Hg	1.5
18,000 feet	380 mm. Hg	2.0
27,000 feet	258 mm. Hg	3.0
34,000 feet	187 mm. Hg	4.0
40,000 feet	141 mm. Hg	5.5

removed the noise hazard for many who fly, the military aviator is not so well protected. He still has to rely on plugging his ears with cotton, which should reduce the noise level to about one-half of its intensity. Molded wax to fit the ear canal and rubber plugs are more effective than cotton. They, however, are uncomfortable and not always so accessible as cotton. When radio reception is required the most satisfactory results are obtained from using a radio headset with earphones in the earflaps of the helmet which are so constructed as to cup the external ear. The exposure to all of the sounds that come over the radio by an earpiece so close-fitting that it prevents any escape of noises will be more likely to damage the hearing than the noises from the propeller and motor. The hearing defect is comparable to that found in telephone operators. It has been suggested that the radio operator use single receptors as the telephone operator does, so that possible damage to his hearing will be limited to one ear. A unilateral radio receptor also would leave an ear free to receive oral messages from members of the crew.

### Conditions Altered in the Sinuses and Middle Ear By Altitude, By Ascent, and By Descent

Being bony cavities, the air spaces of the skull, represented by the nasal accessory sinuses and the middle ears, do not lend themselves to a satisfactory increase or decrease in size to avoid the ill-effects to the expansion and contraction of the air that they contain as a result of the changes in atmospheric pressures. Therefore, a free exchange of air in the sinuses through their openings into the nose and of the air in the middle ear through the eustachian tube is essential to the aviator's well-being. Table 2, showing the approximate values enables one to readily understand the importance of this free exchange of air if damage to the ears and sinuses is to be prevented.

It should be borne in mind that it is not the variation in the pressure and the gas volume or its composition in themselves that cause ill-effects on the body but simply the inequality of the pressure effects existing between the air in the sinuses and the middle ears and that of their surroundings. As to the composition of

air, it remains essentially constant up to 70,000 feet. As you will probably reason, these effects of atmospheric pressure changes on the occupants occur more frequently in descent since descent is relatively faster than ascent. Although this is true in general, the amazing speed of some military aircraft enables such a rapid ascent that the pilot suffers from aeroembolism. The ill-effects on the middle ear and sinuses in ascent have been few as compared with those in descent. The cause might well be that the form of the eustachian tube permits egress of air from the middle ear more readily in ascent than it does the ingress of air to compensate for the decreasing volume of air on descent.

The fact remains that increasing the barometric pressure, whether on descending in an airplane or in a low-pressure chamber, frequently causes ear symptoms and occasionally causes symptoms referable to the sinuses, particularly the frontal sinus. Gemmill<sup>3</sup> reports the following observations on student aviators taking the low-pressure chamber tests:

"The question of earache is a very important one in low-pressure chamber work. Three hundred and five of the 2,521 students complained of earache on these runs. In that group there were only two who had earache on ascent. A preliminary drop of 3,000 feet is made following the ascent of 5,000 feet in order to ascertain if the man can stand descent. This test does produce a few earaches, and the individuals who suffer from these pains are removed from the chamber. The majority of earaches occur at from 17,000 to 14,000 feet on descent. This indicates that an 11,000 foot drop is necessary to elicit pain. One individual did complain of pain at 22,000 feet on the descent. The cure for earache is to stop the run and to ascend 1,000 feet. One method of prevention is the elimination of those who have had recent colds, sinus infection, and sore throats. A quick examination is made of the persons who give a history of any of these conditions. Another method of prevention is to instruct the men in the chamber to stretch their jaw muscles every 400 feet on the descent. No permanent damage was ever observed. Forty-two men had sinus pains. These pains were all frontal sinus pains and all occurred on descent. The onset is generally sudden. In a few cases the pain was very severe. The best method of relief is a quick ascent of 1,000 or more feet. Sixteen complaints of toothache were received. All of these cases were sent to the dental department for examination. Several abscesses were discovered and the infected teeth were removed."

The ear symptoms do not appear to depend so much on the rapidity of the increasing of the

atmospheric pressure as they do on which means are used to equalize the pressure on the inner side of the drum membrane with that of the outer side. When this equalization of pressure is not maintained it results in the complaint of ear fullness, buzzing in the ears, deafness and pain in varying intensity. Inexperienced flying personnel, either as pilots, airplane crew or passengers, are more liable to these ear symptoms because of their lack of familiarity with the means to avoid them. The experienced have learned that relief at the earliest feeling of fullness in the ears usually can be accomplished through yawning, swallowing, moving the lower jaw horizontally with the mouth open or by holding the nostrils closed and increasing air pressure in the nasopharynx. The Valsalva technique may not be effective if it is not begun until after the symptoms of tubal obstruction have passed the mild stage.

Failure to be able to ventilate the middle ear adequately results in observable changes in the ear drum membrane. These variations from the normal may be simply a retraction of the drum and a redness along the handle of the malleus, with mild sensations ranging from a mild degree of stuffiness to that of severe pain when the drum is red and bulging. Even if a drum membrane is fiery red and bulging following a flight, it is unwise to do a myringotomy, unless there is other evidence of infection, because of the dangers of introducing an infection by the treatment prescribed. Even extravasation of blood into the external canal does not alone warrant the diagnosis of a ruptured ear drum.

Schilling and Everly<sup>4</sup> in a comprehensive report on their observations on personnel examined after low pressure tank tests stated: "blood has been noted coming from the external canal or from an eustachian tube and upon examination no complete perforation could be demonstrated." It appears that bleeding may occur within the drum membrane which may rupture internally into the middle ear or externally in the canal without producing a perforation. In a report, Silberstein<sup>5</sup> cited 12 cases of hemorrhages into the tympanum in caisson workers without mentioning a single case of complete rupture of the drum.

The foregoing observations are important because we have relied to a great extent on the appearance of the ear drum as an indication for myringotomy, and also we have considered the presence of a bloody exudate in the external canal, along with redness of the drum membrane, the result of a complete rupture of the drum.

An illustrative case is that of a hostess on an airliner whom I saw two weeks after the ear injury. She gave the following history. On her first flight, on ascent to about 3 000 feet she ex-

perienced severe pain and deafness in her left ear. After landing, she consulted a doctor, who opened the ear drum. Following the operation there was a slight bloody drainage for a few hours. Two weeks later, on examination, the ear drum appeared to be normal, and the hearing was normal.

It is doubtful that the treatment carried out was helpful. Moreover, she was fortunate to escape an ear infection following the myringotomy. Conservative methods in the care of such ear conditions are the most helpful. If the patient cannot inflate his ears easily by the Valsalva method it does not appear advisable to attempt to inflate them through a catheter. When there is an upper respiratory infection, no attempt should be made by any method to inflate the ears, but active treatment of the infection should be carried out. Only a few, if any of us I am sure are in agreement with Poppen's statement<sup>6</sup> that there is little danger of infecting the ears by inflation with the Valsalva technique when one has an acute upper respiratory infection. If there is blood in the external ear canal, irrigations should not be done because of the danger of causing a middle ear infection if the drum is completely ruptured. The symptoms, including the impairment of hearing, usually subside within a few days unless infection develops in the ears.

Damage to the ears occurs more frequently in passengers than in aviation personnel who fly more frequently. This may be attributed to the exclusion on the aviation physical examination of those who have infections of the upper respiratory tract or obstruction from deflection of the nasal septum, polyps, or adenoids, and, also, the ability, learned through experience, to prevent any considerable inequality of pressure on the outer or inner side of the drum. In addition, aviation personnel in the services are exposed to the effects of the low pressure chamber tests, and here a few more candidates are eliminated because they cannot effectively maintain an equalization of pressure in the middle ears and sinuses with the surrounding atmospheric pressure.

In the treatment of aviation personnel, one should avoid, as far as is consistent with good practice, administering drugs that in themselves might render an individual unfit for flying. The sulfonamide group of drugs may occasionally cause mental confusion, impaired sensory perceptions, coordination defects, and other insidious manifestations. Army, Navy, and civilian airlines issue instructions that not only pilots but also other members of airplane crews should be grounded for a period of from two days to six days after the last administration of a sulfonamide drug.

Even pilots of long experience are liable to develop what is called "staleness" by the flight surgeons. This condition is characterized by some of the following symptoms: lack of enthusiasm for flying, lassitude, loss of appetite, slight headaches, sleeplessness, irritability, distractibility, nervousness, and a rapid pulse. Before attributing these symptoms to excessive flying, worries, or instability of the nervous system, a searching physical examination is made, particularly for foci of infection in the sinuses, throat, or teeth.\*

### Discussion

Dr. L. H. Bauer, *Hempstead, New York*—Captain Northington has given an excellent summary of the situation in regard to aviation and the ear, nose, and throat. It is unfortunate that he could not be here to take part in this discussion himself.

The Bárány tests, as Captain Northington indicated, have been discarded except for a very limited use. This has been for two reasons—first, because the Bárány tests give us a poor guide for selecting flyers, and, second, because the labyrinth itself is not the most important factor in maintaining the equilibrium of the pilot. The pilot depends largely on his vision for maintaining his equilibrium. When he is flying blind, he cannot maintain his ship

\* "The opinions or assertions contained herein are the private ones of the writer and are not to be construed as official or reflecting the views of the Navy Department or the Naval Service at large." (Art. 113 (2), U.S. Navy Regulations)

level unless he has been trained to fly by instruments and to disregard the sensations received from his labyrinths. In other words, the labyrinth, after stimulation, gives one false information. For example, it is well known that after being spun to the right and the spinning is stopped, one has a sensation of spinning to the left, unless he can correct this false sensation by his vision. Unless a pilot is trained to fly by instruments, this false sensation from his labyrinths will get him into trouble.

While I agree with Captain Northington that students are less apt to become airsick when soloing, I believe the reason is not so much a question of the presence or absence of fear but rather that the student is so busy flying the ship that he does not have time to think about himself.

Too much emphasis cannot be laid on the dangers of high-altitude flying for those who have blocked eustachian tubes or blocked openings from their sinuses because of congestion. The expansion of gases in the sinuses at high altitudes may cause terrific pain and ruptured ear drums may result on descent unless the pressure can be equalized on both sides of the drums.

The transportation at high altitude by airplane ambulance of patients suffering from sinusitis or middle ear disease is inadvisable, just as those patients with pneumothorax or those who have had recent ventriculography done should not be so transported.

As a whole, the ear, while important in flying, does not hold the place in aviation medicine that otologists tried to make for it during the first World War. Then otologists claimed not only that equilibrium was an ear problem but also that flying was strictly an ear problem. Now we consider neither to be the case. Equilibrium is a function of the whole proprioceptive mechanism, of which the labyrinth is only one part and, in the flyer, not the most important part. Flying is a complex problem in which the ear plays a definite but a lesser role than it was formerly thought to play.

### MEXICO TAKES STEPS TO SUPERVISE DOMESTIC PENICILLIN PRODUCTION

Mexico, which has just acquired three and a half billion units of penicillin from the United States, is taking energetic measures to stimulate and control the production of the versatile new drug in her country. A National Commission for the Control of Penicillin has been organized under government auspices to supervise research and production of the drug and to ensure its most effective use here and its distribution to United Nations fighting men on many fronts.

The three and a half billion units of penicillin were purchased in the United States by the Mexican Department of Public Health for \$140,000, and represent from 3,000 to 6,000 doses, approximately. Part of the supply will be distributed to hospitals in this country, and the remainder will be placed on sale at from \$30 to \$40 per 100,000 units. Penicillin is normally quoted at about \$90 per 100,000 units.

The National Commission for the Control of Penicillin was created at the beginning of this year to serve as an advisory body in recommending the use of the drug and distributing it where needed.

It also serves as a liaison agency with similar commissions in the United States and other American republics. One of its chief objectives at present is to conduct research on types of ailments which are susceptible to successful treatment by penicillin, and research on new and more efficient means of producing the drug in quantities large enough to bring it within the reach of all who need it. The Commission is composed of Dr. Ignacio Gonzalez Guzman, Dr. Jose Zozaya, and Dr. Demetrio Mayoral Pardo.

At present, four laboratories are engaged in producing penicillin in Mexico, and another one, affiliated with a large United States pharmaceutical company, is being planned. Of the four existing laboratories, one is supervised by Mexican experts, another by United States technicians, and the remaining two are still in the process of perfecting their product. All of these laboratories are planning expansion soon for a possible production of several million units of penicillin a day.—*Release from the Office of the Coordinator of Inter-American Affairs*

## DERMATOLOGIC DISEASES FREQUENTLY ENCOUNTERED BY OTOLARYNGOLOGISTS

A BENSON CANNON, M D, New York City

I AM pleased to have this opportunity of relating our experiences with some of the more usual lesions involving the oral cavity. Inspection of the mucous membranes of the mouth, which is a part of every physician's examination, necessarily brings to light many abnormalities which might otherwise go undetected. While most such abnormalities are of a minor order, such as irritations from a variety of local causes, drugs, vitamin deficiencies, lichen planus, or leukoplakia, sometimes the disease is a more serious one, such as carcinoma, syphilis, pemphigus, or the like.

We are consulted almost daily by patients with stomatitis, they usually complain of a sensation of burning, itching, pricking of some part—or the whole—of the mucous membrane, or, again, patients may complain of painful sores in the mouth which interfere with proper mastication.

Frequent symptoms involving the vermilion border of the lip are those of redness, swelling, crustiness, and itching, or even pain. In such cases, we almost invariably search for a local irritant as the cause of the trouble, if the patient is a woman, we first eliminate her lipstick. But the trouble may be due to one of many other irritants, such as dentifrices, mouthwashes, orange peel, salads, perfume in a facial cream or powder, all these are considered and patch tests are made in an endeavor to find the specific cause of the cheilitis. We sometimes see cheilitis in young men who are nervous or mentally unstable and who have the habit of constantly biting the lips and moistening them with the tongue. Long irritation from either or both causes invariably leads to a hypertrophy of the lips accompanied by excess glandular activity which results in crusting and exfoliation. Sometimes when the crust is removed a red, denuded, and slightly painful surface is left. This may prove very troublesome. Little can be accomplished by local treatment other than to keep the parts soothed and to prevent infection. The greatest improvement or cure must necessarily be from psychiatric treatment.

For cheilitis due to other causes we prescribe warm, soothing applications of boric acid, saline, bran, or cornstarch, and in the intervals have the

patient use a soothing protective covering such as albolene, zinc oxide ointment, or Lassar's paste. Usually on removal of the source of the irritation, the improvement is immediate.

Red patches on the mucous membrane, sometimes with superficial central erosions accompanied by burning and pain and usually associated with swelling of the affected parts, should arouse our suspicion of a mouthwash or a gargle such as sodium perborate, dentifrices, a faulty dental plate, or the substance used to cleanse the plate.

Of the eruptions on the mucous membranes caused by drugs, the most commonly seen—by far—is from phenolphthalein. This drug should be remembered as one of the ingredients in a great number of laxatives on the market, it is also contained in certain chewing gums and is to be found as a coloring matter in some dentifrices.

The characteristic lesion from phenolphthalein is a red, swollen erosion or ulcer which may vary from pea-size to a lesion involving the whole side of the cheek or gums. Such lesions are sometimes mistaken for Vincent's angina, pernicious anemia, or are attributed to an avitaminosis.

### Case Reports

Case 1—Mrs. G. B., aged 57, consulted me on June 4, 1942, complaining of an ulcerated, swollen, and painful condition of the gums of the upper jaw and the adjacent side of the cheek of two years' duration. She had seen many physicians in various cities and several dentists, the diagnosis having been made, first, of Vincent's angina, based on the demonstration of Vincent's organisms and also of numerous staphylococci and streptococci. She failed to respond to treatment with antiseptics, including sulfanilamide powder. Four other physicians made a diagnosis of vitamin deficiency and she was put on large doses of vitamin C and B complex and given liver extract concentrate by hypodermic every other day, and twice weekly an injection of staphylococcus and streptococcus vaccine intramuscularly. The patient showed no improvement after being on the above treatment for one month. Treatment was then changed to weekly injections of 0.06 Gm. of mapharsen intravenously. This improved the condition more than anything else.

In June, 1941, the swelling and ulceration of the gums had spread to both sides of the mouth and were very much more extensive, involving the space between the gums and the cheek. Thorough examination of the patient, both physically and from a laboratory standpoint, numerous skin tests for allergy, and physical and neurologic examinations,

Read at the Annual Meeting of the Medical Society of the State of New York Buffalo, New York, May 6, 1943.

Associate clinical professor of Dermatology, Columbia University, New York City.

were made, with negative results. A dentist then made a diagnosis of desquamative gingivitis. He prescribed salt solution. The patient was then sent to a large diagnostic institute where after thorough investigation she was told that her condition was probably an avitaminosis and she was put on large doses of vitamin C, nicotinic acid, and histaminase, which had no effect upon her condition. After three weeks of this treatment, including high vitamin diet, she was advised to have all her teeth extracted. Two teeth were removed before the dentist remarked that her teeth were perfectly sound and in remarkably good condition and advised against the removal of more. The patient was fairly healthy and strong and showed no signs of constitutional disease other than the mouth condition. She then was given an autogenous vaccine of streptococci and staphylococci in large doses, the dose at each injection being increased every four days. She also used sodium perborate alternating with nearsphenamine powder. The patient improved somewhat on this treatment but had relapses.

Examination disclosed a well-developed and well-nourished healthy-looking woman, not apparently ill. The gums, more especially on the left side along the molars, and the intervening spaces between the gums and cheeks were swollen, dark red, spongy, ulcerated, quite painful to touch, and bled easily on motion. The teeth were unusually good, clean, and sound in appearance. A diagnosis of drug eruption—phenolphthalein—was made. The patient readily admitted having taken alophen pills every night for severe constipation for at least six years. The drug was stopped, the patient was given a saline irrigation of the mucous membrane of the oral cavity, the affected parts were painted with 15 per cent argyrol for a few days, and a suitable diet was prescribed for the constipation: forced fluids and some milk of magnesia or cascara. The improvement was immediate and within two months her mouth was cleared.

Not many weeks ago, I was asked to see a 64-year-old patient in consultation at one of our large hospitals. She had painful sores studded over the mucous membranes of the mouth, hard palate, and tongue, these varying in size from that of a large pea to that of a dime. They were deep red and eroding in the center, the color fading at the margins. She had had the sores for several months; they would improve and then recur. She was under treatment for a secondary anemia. Again we suspected a phenolphthalein condition, but the attending physician said the patient had been in the ward for six weeks and had had no phenolphthalein—only such medication as the doctors there had prescribed. But upon examining her chart, we discovered that the patient had had an alophen pill (containing phenolphthalein) under the doctor's orders every night since her admittance.

Sometimes luminal causes lesions of the mucous membranes of the mouth, usually of the bullous

erythema multiforma type. Only a few lesions are present and when the bullae have ruptured, the swollen, red, and denuded areas may resemble a phenolphthalein eruption, as may also the bluish-brown pigmented macular areas on the body.

There is a growing tendency among physicians to ascribe every variety of mucous membrane lesion to vitamin deficiency. Undoubtedly, avitaminosis is very commonly expressed in change in the mucous membranes of the mouth; namely, a change in color (erythematous patches of orange-red to deep bluish-red), fissuring at the corners of the mouth and split papules at the angles of the mouth, scaling of the skin of the lips and surrounding parts somewhat suggestive of monilial infection, redness and desquamation, atrophy and leukoplakia of the tongue. Oftentimes such individuals are below par physically, tire easily, have a secondary anemia, or actually suffer from some constitutional disease.

Gross<sup>1</sup> calls attention to atrophy of the mucous membrane of the mouth and pharynx, and more clearly on the tongue which, in typical cases, is completely smooth, owing to avitaminosis. I have seen so-called experts in vitamin study show slides with tongue lesions typical of syphilis (such as leukoplakia, atrophy, scarring, and interstitial glossitis) as examples of avitaminosis. I also have seen many drug eruptions on the mucous membranes of the mouth and lichen planus—both treated for months as avitaminosis.

Lichen planus is a fairly common skin disease, and, in addition to the cutaneous lesions, the mucous membranes also are usually involved, or it may be present only in the oral cavity. The lips, the mucous membranes of the cheeks and tongue, and sometimes the hard palate are affected. Characteristically, these lesions appear white, lacy, annular and linear, and slightly raised, somewhat resembling leukoplakia—sometimes superficial, eroded, and ulcerated lesions appear which are sometimes suspected of being syphilitic, tubercular, or carcinomatous. Lichen planus of the oral cavity is more resistant to treatment than are the skin lesions, but if the lesions are cauterized every five to seven days with 25 per cent silver nitrate or with an acid, in addition to the systemic treatment with mercury or arsenic, they will invariably disappear within from six to eight weeks. I think it important that one remove all foci of infection and build up the patient's general health. We recognize the typical lichen planus, clinically and histologically, involving the mucous membrane of the oral cavity and lips as well as cutaneous surfaces, following arsphenamine injections. This type responds to the elimination of arsenic from the system (Fig. 1).

FIG. 1. Lichen planus ulcer of the tongue, simulating carcinoma.

Leukoplakia is another of the conditions more frequently found on the mucous membranes of the oral cavity—more usually on the tongue, the mucous membrane of the cheeks, or on the gums and lips. It is thought to be due to a variety of causes, local as well as constitutional. We recognize the smoker's leukoplakia, which is more apt to occur just inside the corners of the lips and sometimes on the tongue—or the leukoplakia may be due to a dentifrice or to irritation from a tooth, bridgework, or an ill-fitting plate and poor hygiene of the oral cavity. Fig. 2 shows leukoplakia of the lips, cheek, and tongue. The mouth showed a very unsanitary condition, with a marginal gingivitis throughout. The patient was put on monthly dental prophylactic treatment. The lesion of the tongue changed markedly. It has since become very diffuse and more like a fog than a patch. The patient's general health is greatly improved. So little is known of the cause of leukoplakia that dental treatment was administered more for the sake of general hygiene rather than in the hope that it might have a beneficial effect upon the disease. When one removes the cause, oftentimes the lesions will disappear, if they have not become too thickened and verrucous.

I have observed several patients suffering from an extensive leukoplakia of the tongue and mucous membrane of the cheeks associated with atrophy, erythematous patches, and fissures at the corners of the lips, and also associated with leukoplakia and atrophy of the mucous membrane of the labia and vaginal wall, the latter condition known as kraurosis vulva. The patients have had a moderate degree of anemia, complained of tiring easily, and shown negative Wassermann reactions. Improvement has been decided upon the administration of progyon and vitamin B and riboflavin by mouth. It is this type of leu-

FIG. 2. Leukoplakia, improved by oral hygiene.

koplakia, associated with some constitutional conditions, in which one would expect to—and, I believe, does—receive the greatest response with a treatment of suitable diet and vitamins.

Rhoads<sup>2</sup> referred to a Plummer-Vinco syndrome associated with kraurosis vulva as partly due to avitaminosis.

We also recognize leukoplakia as being a symptom of syphilis, in which case it is usually limited to the dorsum and borders of the tongue and cheeks opposite the last two molars, and lips, and associated with scarring and an enlargement of the tongue. These three symptoms give a diagnostic picture of syphilis.

*Case 2.*—Mr. J. R., aged 40, was referred to me in April, 1931, because of a white, thickened, eroded condition of the lip, tongue, and mucous membranes of the mouth of thirteen months' duration (Fig. 3). He denied having venereal disease. He had been married for seventeen years. His wife was living and well. She had three children, ages 9, 11, and 13 years, all well. There had been no other pregnancies. The patient's past and family histories were essentially negative. He had first noticed a small white area in the left corner of his mouth that had gradually spread over both the upper and lower lips, the tongue, and the mucous membranes of the mouth. For several weeks the lower lip on the left side had been much thickened, white, and covered with a hard, thick crust. His general physical examination was essentially normal. His blood pressure was 150/86. There were no cardiac enlargement, no murmurs, accentuations of sounds, nor

FIG. 3. Leukokeratosis of the lips, tongue, and mouth due to syphilis.

irregularity. The abdomen, liver and spleen, pupils, and the deep reflexes of the upper and lower extremities were normal. There was an extensive leukokeratosis of the entire lower lip, which was most marked on the left half. This latter portion was whitish in color, verrucous, greatly thickened, and covered with a thick adherent crust. The mucous membrane of the tongue and cheeks showed an extensive leukoplakia that was verrucous in places. The tongue was large and firm and there were several streaks of atrophy and scarring of the tongue. The patient's blood Wassermann was checked on two different occasions and was strongly positive, both for cholesterin and alcoholic antigens and the Kahn precipitation test. His spinal fluid was negative in all phases.

I gave him five weekly injections of arsphenamine and five muscular injections of mercury salicylate. There was tremendous improvement in the leukoplakia of the mucous membranes of the tongue and cheeks and lips, except for the verrucous leukokeratosis on the left side of the lower lip. This had shown no appreciable change, so that area was removed with the desiccating needle and the patient was then sent back to his physician for continuance of his antisyphilitic treatment. The result of both the operation and the antisyphilitic treatment was excellent.

In untreated leukoplakia, carcinoma is quite likely to appear, particularly if the cause of the lesions is not eliminated. We advocate the removal of every thickened and verrucous leukoplakia with the electric needle as a precaution against carcinoma. It has been my practice to desiccate the leukoplakia areas under a local anesthetic so that the whole mucous membrane will appear raised, white, and soggy. I then take hold of the mucous membrane with a pair of forceps and pull it off in sheets as one would the bark of a tree. This treatment leaves a smooth red surface which granulates over within about two weeks. Sometimes there is a recurrence of a small pea-sized lesion, which I desiccate in the same manner.

FIG. 4. Extensive leukoplakia with atrophy of the tongue and mucous membranes of the mouth, accompanied by leukoplakia and atrophy of the labiae and vaginal mucous membranes (kraurosis vulvae), successfully treated with vitamins.

Over a period of many years I have successfully treated a number of cases with the above method and I have never seen any secondary untoward results. On the other hand, I have seen two patients develop a rapidly growing carcinoma within a few weeks after having been treated with a suberythema dose of radium.

Whatever the method used for removal of leukoplakia or a leukokeratosis, it should be thorough.

*Case 3.*—Mrs. F. F., aged 50, consulted me on March 10, 1942, complaining of white spots and soreness of the mucous membranes of the mouth and tongue and of the labiae and vagina, of several months' duration. Her past and family histories were essentially negative. She had been married for many years, never pregnant. She had first noticed white spots on the tongue and then a sensation of soreness in the mouth on taking sharp foods. She then developed a leukorrhea. It was quite profuse and annoying. She consulted her physician, who investigated her condition and prescribed alkaline douches and stilbesterol by mouth and injections. Examination to determine the cause of the bloody vaginal discharge was essentially negative except for

the local condition. Stilbesterol was discontinued and the bleeding ceased within ten days. She was then referred to me for the condition of the mucous membranes of her oral cavity and of the vaginal mucous membranes. She had been perfectly well except for moderate secondary anemia and tired easily on exertion. Her general physical and neurologic examinations were otherwise essentially negative, as were also her blood Wassermann, urine analysis, and blood chemistry. The basal metabolism was reported to be within normal limits.

The mucous membranes were found to be milky white, as though they had been painted with silver nitrate solution. There were many streaks that were faintly raised and in the involved spaces were desquamation of the epithelia of the mucous membranes of the cheeks and tongue, giving a smooth shiny, atrophic appearance. There was also an extensive leukoplakia involving the mucous membranes of the labiae and vaginal wall, associated with a smooth, shiny, yellowish red condition of the vaginal mucous membrane, studded here and there with a few bright-red, pea sized spots. The condition appeared atrophic (Fig. 4).

She was then given crude liver injections, 2 cc twice a week, riboflavin to take by mouth, 15 mg three times a day for three days, after which 3 mg were given three times a day and vitamin B complex to take by mouth, beginning with 6 mg a day and gradually decreasing to 3 mg a day. There was gradual pronounced improvement in the mucous membranes of both the mouth and vagina. The discharge entirely ceased and the white leukoplakia like condition disappeared, leaving only red atrophic mucous membranes. The patient generally feels greatly improved. She has gone for six and one-half months without any symptoms.

#### Diagnosis Leukoplakia kraurosis vulvae

Favorable results in the treatment of leukoplakia by the use of vitamin B have been recorded. An interesting discussion of the matter was given by Martin and Rhoads<sup>3</sup> in *Cancer Research*.

We know that syphilis nearly always involves the mucous membranes in the secondary stage of the disease and oftentimes in the tertiary stage. The extragenital lesion of syphilis is probably more often found on the lips than any other place, though it may occur on the tonsil, tongue, or gum. We should always be suspicious of a hard, raised lump of recent origin involving any part of the oral cavity, and should the lymph gland draining the affected area become swollen, we can be fairly confident of a diagnosis of chancre. I believe it rarely occurs that a physician other than a syphilologist recognizes an extragenital chancre until a secondary eruption appears and makes him suspect syphilis. Secondary syphilis in the form of mucous patches over the membrane of the oral cavity is to be found in the great majority of cases. Sometimes there are

only fissuring or split papules at the corners of the lips or a sharply limited erythema of the pharynx extending across the soft palate, or, again, the patient may have very large tonsils which almost meet across the posterior walls of the pharynx. This is often diagnosed as a follicular tonsillitis.

These primary and secondary lesions usually contain spirochetes in great numbers and, consequently, may be a great menace to the examining physician and to others with whom the patient may come in intimate contact.

Gumma may involve any portion of the oral cavity, but we probably see more cases of the hard palate than of any other location. Usually the gumma begins as a localized swelling and redness, gradually breaking down in the center, forming a deep ulcer with necrosis of the hard and soft palate and perforation into the nasal septum. An enormous amount of destruction of tissue may take place within a few hours to a few days, so it is imperative that an early diagnosis be made and treatment begun as quickly as possible.

A few years ago an otolaryngologist referred to me a patient who had a gumma of the hard and soft palate with a small perforation, the latter having developed overnight. The physician had observed this patient for over a year and had treated him for several attacks of redness and swelling. He had taken a specimen of the tissue for biopsy study, the pathologist reported a probable tuberculosis. The patient's blood Wassermann had been reported negative. The patient was sent to Saranac Lake for six months, returning to New York with complete recovery. A few months later, he had a recurrence of the same swelling, so the physician gave a light treatment to the swollen area, and it was on the next day that I was asked to see him for the perforation.

A

became 4+ twenty four hours after an injection of arsphenamine. The ulcer healed rapidly under antisyphilitic treatment leaving only a hole in the hard palate about the size of a lead-pencil rubber.

A patient with gumma involving the posterior wall of the larynx called me on the telephone a short while ago, stating that his otolaryngologist had made a diagnosis of probable carcinoma. He said that several Wassermann tests done by laboratories had been negative, but as I had treated him for syphilis some eight years previously, he would like my opinion. The patient did have two gummatous lesions, one just above the other, the upper one being about the size of a 25 cent piece and the lower one-half that size. I removed a piece of the tissue with a Coakley punch for histologic study, took blood for a Wassermann, and gave the patient an injection of

FIG. 5. Lip treated with radium for carcinoma, followed by sloughing. Note leukoplakia and atrophy of tongue.

arsphenamine. Twenty-four hours later, both ulcerations were noticeably improved. The first blood Wassermann gave a negative reaction, while a second one taken twenty-four hours after the arsphenamine injection was 4+.

I have made it a rule to take a section for biopsy from all suspected cases of gumma, and if there is no evidence of carcinoma I give the patient a provocative dose of arsphenaminé.

Gumma of the tongue is relatively rare, but as a rule it is not difficult to diagnose, in that the tongue is usually swollen and red, with deep sinuses and sloughing. There is very little or no hardness around the lesions and they are usually not painful. The patient usually has other evidences of syphilis, such as scarring or leukoplakia, a history of syphilis, and often a positive Wassermann test.

There was a patient admitted to the City Hospital two years ago who had received two radium treatments at one of our large New York cancer hospitals for a diagnosed carcinoma of the lip. There was enormous swelling and ulceration following the treatment and the patient was told that this was the reaction to be expected and to return for another radium treatment. Meanwhile, a great part of his lip had sloughed away. There was no evidence of a burn and the lesion did look like a gumma. His blood Wassermann was returned moderately positive, becoming strongly positive after the first arsphenamine injection. The lesion healed rapidly under anti-syphilitic treatment. It was probably the leuko-keratosis associated with the gummatous lesion which made the diagnosis of epithelioma seem the correct one. Had the physician examined the

FIG. 6. Carcinoma of the tongue simulating gumma. Note leukoplakia and scarring and glossitis characteristic of syphilitic infection.

patient's tongue, he would have seen unmistakable evidence of syphilis—leukoplakia, scarring, and interstitial glossitis (Fig. 5).

Carcinoma of the oral cavity is of comparatively frequent occurrence in dermatologic practice. The squamous cell epithelioma of the lip is more frequently encountered, especially of the lower lip, although we see carcinoma of the tongue, tonsils, and gums occasionally during the course of a year. All squamous cell epitheliomas of the mucous membranes can usually be attributed to some irritation of long standing—the pipe-smokers' epithelioma of the lip, keratoses of the lip arising from irritation from sunburn or from chapped lips, leukoplakias, the epithelioma of the tongue or side of the cheek from irritation from a ragged tooth. Occasionally the gums may be the site of a carcinoma from an ill-fitting plate. The tongue with leukoplakia, atrophy and glossitis as a result of syphilis is not infrequently the site of carcinoma that is almost invariably mistakenly diagnosed and treated as gumma until the carcinoma has metastasized. I have made it a practice in such cases of syphilis of the tongue accompanied by a strong plus Wassermann reaction to take a section for biopsy before giving any syphilitic treatment (Fig. 6).

*Case 4.*—Mrs. H. E. D., aged 47, was seen in consultation with a physician on May 8, 1942, complaining of a painful ulceration on the right side of the tongue of five months' duration. Her family and

past histories were essentially negative. She had been married for twenty two years but had never been pregnant. The lesion began as a small pea-sized white spot on the right border of the tongue about two inches back of the tip and gradually increased in size, becoming ulcerated and painful about three weeks after onset. The affected side of the tongue became increasingly swollen, painful, and ulcerated, so that during the preceding three or four weeks she has been unable to rest without taking sedatives, has lost considerable sleep, was unable to open her mouth wide, and the soreness and pain had been so great as to prevent proper mastication of food. She felt ravenously hungry but could not eat. Even during sleep, if her tongue fell to the right side of her mouth, the pain of the tongue resting against her teeth awakened her. She also felt a soreness in all of her teeth and in her right jaw. Diagnosis was made as probably Vincent's angina, and antiseptic mouth washes and gentian violet were used. After two months she was unable to protrude the tongue because of a pulley like band underneath. She had lost 5 pounds in weight in the preceding month, which she thought was caused by being unable to eat.

Examination revealed a well-developed and fairly well nourished woman, not acutely ill with an anxious expression, but apparently in no acute pain. Her general physical and neurologic examinations were essentially negative, as were also her routine blood count, Wassermann tests, and urine analysis. The ulceration on the tongue involving the right border measured  $5\frac{1}{2}$  by  $2\frac{1}{2}$  cm and extended downward beneath the tongue on the edge of the floor of the mouth and forward to and along the frenum of the tongue to within about  $3\frac{1}{2}$  cm of the tip. The base of the ulceration was irregular, with islands of split-pea sized, red, granular, and bleeding points, and between these a sloughing base. The borders were sharply defined, elevated, and hard. The right submaxillary gland was the size of a hazelnut, hard, not tender, and freely movable. The tongue could not be protruded nor could she open the mouth for more than about  $1\frac{1}{2}$  inches. Biopsy showed squamous cell carcinoma.

Diagnosis: carcinoma of the tongue with metastasis.

The patient was referred to the surgical department of one of our large hospitals, where she was given radium treatment to the tongue and deep roentgen ray therapy to the glands of the neck and beneath the jaw. She died on April 11, 1943, with general carcinomatosis.

While some carcinomas of the mucous membranes are more malignant than others—due to the type of growth, the age of the patient, or whether or not it has formed within scarred tissue—they all necessarily have a grave prognosis and should be treated only by a physician or surgeon skilled in dealing with new growths.

Dr. Douglas Quick<sup>4</sup> stated that while radium irradiation represents the backbone of the treatment of the primary growth in the oral cavity,

Fig 7 Pemphigus of the lips with ruptured bullae erosion, and crusting of the lips

oftentimes operative surgery is necessary as well as x-ray radiation.

The initial lesion of pemphigus (Fig. 7) is sometimes found in the oral cavity and is considered a sign of rapid and fatal termination. I have known several patients to die within six to eight weeks from the time the first bulla appeared on the mucous membranes of the mouth. Pemphigus is usually not difficult to diagnose, one or more bullae appearing on the mucous membranes and varying in size from that of a dime to one covering the whole cheek and gums, or even the entire oral cavity may be involved. The bullae are very thin and rupture quickly, leaving a raw, bleeding surface with ragged mucous membrane at the edges. The denuded areas are very painful, become necrotic, and emit a foul odor. The pharynx, larynx, and esophagus may become affected. Only liquids can be taken, and those with difficulty. Patients with pemphigus usually have constitutional symptoms of weakness, are easily fatigued, feel ill, and have an anxious, worried expression. Even in the early stages of the disease the sufferers have a feeling of impending danger. Potassium permanganate in tepid solution will keep the parts clean, is soothing, and acts as a deodorant. Physiologic saline is also beneficial when used to irrigate the oral cavity. Pemphigus of the body may not appear until one to several weeks after the mouth lesions. No treatment has proved to be curative. I have recently successfully treated a severe case of pemphigus in a 63-year old man in which the prognosis appeared hopeless, by giving vitamin D and estrogenic hormones. He has been free of all lesions for approximately five months.

Drs. Talbot and Coombs<sup>5</sup> have used saline intravenously and suprarenal cortex hormone with encouraging results.

Alkalis, arsenic, and germanine have all been tried with some benefit.

The patient received 150,000 units of vitamin D three times a day for about nineteen weeks, and 50,000 units of estrogen intramuscularly twice a week for about five times, then changed to stilbesterol by mouth because of the expense of the drug for hypodermic use.

### Summary

The recognition and treatment of some of the commonly seen minor disorders of the oral cavity, such as lesions from local irritants, drugs, vitamin deficiencies, lichen planus, and leukoplakia, and three of the more serious diseases—syphilis, carcinoma, and pemphigus—are discussed.

The local and constitutional causes of leukoplakia are discussed, with the effect on the lesions upon removal of the local irritant responsible for the conditions. A type of leukoplakia was recognized as probably due to vitamin deficiency, and improvement in the lesions was noted following treatment with vitamins.

The removal of verrucous leukoplakias with

the electrical needle is advocated as a precaution against the development of carcinoma.

Early recognition of carcinoma of the oral cavity is discussed, and a biopsy recommended as a means of diagnosis in all cases suspected of being carcinoma.

### Discussion

Dr. Walter L. Mattick, *Buffalo*—I have enjoyed immensely the paper and the kodachrome reproduction of the various lesions commonly encountered around the nose and oral cavity. The Society is to be congratulated on having had such a rare opportunity.

### DEPARTMENT OF MEDICAL SCIENCES AT BROWN

The establishment of a Department of Medical Sciences at Brown University was announced on July 12 by President Henry M. Wriston. This department will perform a number of important functions within the University and in the relationships of the University to the medical profession and hospitals of the community.

Charles A. McDonald, M.D., and Alex M. Burgess, M.D., physicians connected with the Division of University Health for some time, have been appointed professors of health and hygiene.

Dr. Wriston pointed out that through this department the University will assume a larger responsibility for the general education of its students in matters of health as a requisite of effective accomplishment in college and in after-college years. "It will approach this responsibility in the light of the needs which have been revealed by the war experiences,"

he said. The president went on to say that special attention will also be given to the orientation of students who are planning professional study in the art and science of medicine.

"The Department of Medical Sciences will also offer facilities for advanced study and research," Dr. Wriston said. "This is designed in part to meet the needs and desires of recent graduates of medical schools whose postgraduate studies in certain specialized fields of medical science have been interrupted by war service."

The president stated that opportunities for specialized study will also be available to other interested members of the medical profession. He emphasized that Brown University is also prepared to cooperate in the development of programs of postgraduate study and research for members of the resident staffs of the hospitals of the community.

### "SALIVARY AMYLASE AND DENTAL CARIES"\*

To the Editor [of the *J.A.M.A.*]:—In the May 6 issue of the *Journal* the editorial entitled "Salivary Amylase and Dental Caries" properly emphasizes the significance of the findings that a direct relationship exists between the diastatic activity of saliva and the incidence of dental caries. However, credit for the discovery is misplaced. It should have been given to Florestano, Faber, and James (*J. Am. Dent. A.*, Vol. 28: 1799, Nov., 1941), whose

complete paper on the subject appeared well over two years ago. The editorial does not mention these workers but gives all the credit to Turner and Crane (*Science*, Vol. 99: 262, March 31, 1944), whose preliminary paper was published less than two months ago. Probably the oversight was due to the failure of Turner and Crane to cite the paper by Florestano and his associates. Whatever might be the reason for the error, attention should be called to this correction.—Harry G. Day, Sc.D., *Department of Chemistry, Indiana University, Bloomington, Ind.*, in *J.A.M.A.*, June 17, 1944

\* The original item on this subject was reprinted in this *JOURNAL* in the July 1, 1944, issue, page 1484.

# REINFORCEMENT OF SULFONAMIDE ACTIVITY: EXPERIMENTAL AND CLINICAL OBSERVATIONS

ERWIN R. NETER, M.D., Buffalo

THE greatest and most important step forward in the field of chemotherapy since the pioneer work of Paul Ehrlich (apart from the studies of Fleming on penicillin) is the discovery by Gerhild Domagk of the therapeutic activity of prontosil in experimental streptococcal infections of mice. In man, too, this compound proved to be a reliable chemotherapeutic substance effective in certain microbial infections. Domagk's publication stimulated experimental and clinical research throughout the world in an unparalleled manner. At first, prontosil was believed to be a specific agent effective only in vivo. Later it was established beyond doubt that sulfanilamide is the directly effective compound with bacteriostatic properties both in vivo and in vitro. Certain bacterial infections, however, did not respond to treatment with these drugs. Research, therefore, was primarily directed toward the synthesis of new compounds with a broader range of activity. It is well known that this endeavor was crowned with success. Sulfapyridine, sulfathiazole, sulfadiazine, sulfaguanidine, and sulfasuccidine are the results of these investigations.

There is another method of approach to increasing the effectiveness of sulfonamides—namely, by a suitable change of the environmental conditions and by the combined use of the sulfonamide compounds with other antimicrobial agents. It is proposed to discuss here the pertinent data of these experimental and clinical investigations. The presentation will be concerned with (1) potentiation of sulfonamide activity by other agents which per se do not exert antimicrobial activity and (2) with synergistic effects resulting from the simultaneous use of sulfonamides and compounds which, employed alone, exert bacteriostatic, bactericidal, or antitoxic effects.

## Effect of Temperature on Sulfonamide Activity

In vitro experiments by several investigators, including Wengatz, Boak, and Carpenter,<sup>1</sup> White,<sup>2</sup> Spink,<sup>3</sup> Weld and Mitchell,<sup>4</sup> and Neter,<sup>5</sup> revealed that sulfonamide activity can be markedly enhanced by raising the environmental tem-

perature. With certain micro-organisms the increase in antibacterial activity of sulfonamides is manifold if the temperature is changed from 37 C to 39 C. Even bacterial species which appear to be rather resistant to sulfonamides, such as the enterococcus or streptococcus fecalis, become susceptible at higher temperature (43 C). These experimental observations have been applied to the treatment of man. Belt and Folkenberg,<sup>6</sup> reported, for instance, that 86 per cent of patients with sulfanilamide-resistant gonorrhea were cured by combining chemotherapy and thermotherapy.

## Synergistic Action of Sulfonamides and Immune Serums

The problem of synergism of specific antibodies and chemotherapeutic substances has been the subject of many experimental investigations. In certain instances the combined use of these agents exerts by far greater antimicrobial activity than that of either agent alone. A very thorough series of experiments was carried out by Branham and Rosenthal.<sup>7</sup> These authors studied the effect of serum and sulfanilamide, alone and in combination, in experimental meningococcal infections of mice. The mortality rate of untreated mice was 100 per cent. Treatment with sulfanilamide alone resulted in a death rate of approximately 70 per cent, whereas treatment with serum alone lowered the mortality rate to 90 per cent. On the other hand, combined treatment with both sulfanilamide and serum resulted in recovery of all infected mice. In experimental pneumococcal infections too, the combined treatment with sulfonamides and specific antibodies yielded better results than therapy with one agent alone.

Clinically, the combination of chemotherapy and serum therapy has been used in certain infections in the past, particularly in pneumococcal and meningococcal infections. Recently, very encouraging results were reported from the use of type-specific (rabbit) serum and sulfonamides in infections due to *Haemophilus influenzae* type B. Alexander, Ellis, and Leidy<sup>8</sup> reported a series of cases of meningitis thus treated with a mortality of only 26 per cent contrasted with a mortality rate of over 90 per cent in untreated cases. At this hospital, too, favorable results have been obtained with this treatment. Of 20 consecutive cases of meningitis 14 (70 per cent) of the patients recovered and 6 (30 per cent) died. Not included in this series are patients who died with-

Read at the Annual meeting of the Medical Society of the State of New York, Buffalo, May 5, 1943.

From the Bacteriologic Laboratories of the Children's Hospital and from the Department of Bacteriology and Immunology, University of Buffalo School of Medicine, Buffalo, New York.

sulfonamides used in conjunction with immune serums, pyridium, and azochloramid are discussed. The phenomenon of synergism of sulfonamides and other agents deserves further experimental and clinical investigations.

### Discussion

Dr. Thomas S. Bumbalo, *Buffalo*—In no branch of medicine or surgery has the value of the sulfonamides been more striking than in pediatrics. Mortality rates of many of the infectious diseases of children have been cut appreciably, periods of convalescence have been shortened, and some of the more serious complications, notably, empyema complicating pneumonia, have become fewer. In the face of all this, however, we must admit that the sulfonamides are not the complete answer in many situations where we expected them to be the answer. This winter, for example, we treated at least a dozen cases of typical and atypical pneumonias in children that did not respond to the sulfonamides. Some few failed to respond even after specific rabbit serums were used. This, I am sure, has been the experience of many clinicians and the incentive for the type of research reported by Dr. Neter.

Among the early reports of potentiation of the sulfonamides by other agents was the report by Bierman and Bach\* in 1941 of 2 cases of subacute bacterial endocarditis successfully treated with sulfanilamide and physically induced pyrexia and sulapyridine and physically induced pyrexia. Again, in 1941 Lichtman and Bierman reported on the combined methods of treatment of subacute bacterial endocarditis. They reported 43 cases treated with chemotherapy and heparin, with 5 recoveries;

26 cases treated with chemotherapy and hyperthermia, with 4 recoveries; and 21 cases treated with chemotherapy and hyperthermia induced by the intravenous injection of typhoid-paratyphoid vaccines, with 5 recoveries—a 25 per cent recovery rate. They also reported 6 cases treated with chemotherapy and radium therapy with one recovery. We recently treated a boy 6 years old, with a streptococcus viridans, subacute bacterial endocarditis superimposed on a coarctation of the aorta, with sulfathiazole and typhoid-paratyphoid vaccine intravenously, with what appeared to be very encouraging results. After seven days of normal temperature and marked clinical improvement he died abruptly of what appeared to be a ruptured esophageal varicosity with fatal hemorrhage. We were not able to obtain consent for an autopsy examination to prove our impressions.

One of the infections in which the results have been consistently favorable with the sulfonamides is meningococcus meningitis. However, the more severe cases of this disease illustrate well the favorable results obtained by the synergistic action of the sulfonamides and immune serum. At the Meyer Memorial Hospital we use the combined chemotherapy and serum treatment with most satisfactory results. In 1929 before the advent of the sulfonamides we treated 19 cases of meningococcus meningitis with serum alone with 11 recoveries; in 1930, 11 cases with 8 recoveries; in 1931, 3 cases with 2 recoveries; in 1932, 6 cases with 4 recoveries; in 1936, 12 cases with 8 recoveries; in 1937 (combined serum and chemotherapy) 21 cases with 19 recoveries; in 1938 (combined serum and chemotherapy) 18 cases with 12 recoveries; in 1939, 6 cases with 5 recoveries; in 1940, 4 with 2 recoveries; in 1941, 9 with 9 recoveries; in 1942, 4 with 3 recoveries.

While the results obtained in the treatment of meningococcus meningitis with chemotherapy alone are very favorable, we believe that our lower mortality rate obtained with the combined therapy is a little lower than most results, reported in the literature, with chemotherapy alone.

Since 1929 we have seen 96 cases (both adults and children) of pneumococcus meningitis with only 2 recoveries; one in a child treated with serum alone before the advent of the sulfonamides, the other an adult treated with both serum and chemotherapy.

Since 1922 we have seen, at the Meyer Memorial Hospital, 49 cases of influenzal meningitis with 8 recoveries, all since 1937, treated with chemotherapy alone. Two children treated with combined chemotherapy and Alexander's rabbit serum died. Unquestionably, the sulfonamides are directly responsible for this favorable change in the prognosis of influenzal meningitis, which in our hospital was 100 per cent fatal before the advent of the sulfonamides. These changes constitute one of the most striking achievements in modern medicine. All of these favorable results perhaps can be further improved by either the potentiation of the sulfonamides by other agents, physical or chemical, or by the use of chemotherapy together with serums or other biologicals, natural or perhaps synthetic, that will have a favorable synergistic action.

# THE RESULTS OF CANCER TREATMENT

CHARLES E. FARR, M.D., New York City

SOME years ago—in 1919, to be exact—a survey was made of 103 cases of malignant disease at the New York Hospital, service of Dr. Charles L. Gibson, during a period of about eighteen months—cases in which a record had been kept of the duration of symptoms and the various reasons for delay in seeking treatment.<sup>1</sup> The results were as follows:

Average period from onset of symptoms to first consultation, 3.19 months

Average period from first consultation to entrance into hospital, 8.7 months

Total delay, 11.89 months

The same cases were then grouped by curability and the advice given by the first physician consulted in each case was tabulated. Advice was considered right when operation was urged, other advice was counted as wrong. Tabulation of advice follows:

		Advice Given	
		Right	Wrong
Incurable cases	48	16	32
Probably curable cases	35	17	18
Curable cases	18	11	7
Totals	101	44	57

In 1938 Dr. George T. Pack and Dr. James S. Gallo<sup>2</sup> reported the results of a study of 1,000 case records in Memorial Hospital, New York, and the Paterson (New Jersey) General Hospital, their object being to determine responsibility for delay in the treatment of cancer. They showed that 44.3 per cent of delay was due to the patient alone, 18.0 per cent to the patient and doctor together, 17.0 per cent to the doctor alone, and in 20.7 per cent of cases no delay occurred.

Again, in 1942, Dr. Charles R. Harms and his associates, with the same object in view, interviewed 158 cancer patients admitted to the New Haven (Connecticut) Hospital or Tumor Clinic. They reported<sup>3</sup> that in only 3 of these cases (1.9 per cent) was there no delay, and that in the remaining 155 cases 54.8 per cent of delay was due to the patient alone, 27.8 per cent to the patient and doctor together, 17.4 per cent to the doctor alone.

The last figure is almost exactly that reported four years earlier. In view of the great importance of early diagnosis and prompt treatment if cancer is to be controlled, these evidences of delay due to the doctor are of startling significance.

Chairman Special Committee on Cancer Control Medical Society of the County of New York

All of these surveys suggest the need for further action along the two lines of education of the laity and education of the physician. Education of the lay public is being carried on by the American Society for the Control of Cancer and its branches throughout the country.

Education of the doctor should be carried on inside the profession itself. To the writer it would appear that the failure on the part of some doctors is due not to neglect or ignorance of early symptoms, but rather more to the feeling of helplessness and hopelessness with which far too many family practitioners still regard cancer. Is such a feeling justified? The writer thinks not.

Let us look at the figures. In early cases of cancer the percentage of five-year cures reported by reliable authorities is as follows:

Cancer of the lip	85 per cent
Cancer of the skin	80 per cent
Cancer of the body of the uterus	80 per cent
Cancer of the breast	75 per cent
Cancer of the cervix uteri	65 to 70 per cent
Cancer of the tongue	40 per cent
Cancer of the stomach	22 per cent

These figures, coming from authorities who see large numbers of cancer patients and who are therefore in a position to speak, certainly justify greater optimism than is expressed by many practitioners. The problem is exceedingly difficult, and because of many factors—age and other disabilities—it is not to be hoped that 100 per cent curability will ever be reached. But in accessible cancers in which early diagnosis is possible a high rate of cures should and could be obtained.

Even in fairly advanced cases the situation is not hopeless and the feeling of despair which is prevalent among the family doctors must be overcome. This feeling is undoubtedly the reason why so many patients are not given a proper chance. Every surgeon of experience has in his case files many examples of seemingly hopeless cancers apparently cured for years. For instance, a woman who had first one, and after a seven-year interval, the other breast removed, in each case with a very large cancerous growth, more than twenty-five years later was still alive and well.

It is true that within the past thirty years the death rate from cancer has increased from 82.1 per 100,000 of population to 160.5, but striking increases occurred also during the same period in diseases of the circulatory system—from 242.1 in

1912 to 373.0 per 100,000 in 1941—and in diabetes—from 17.5 to 40.7. These large increases in mortality from diseases affecting chiefly the older age groups were to be expected, since with the reduction of mortality in the earlier decades of life the percentage of population in the older groups becomes much larger, and of course healing potentialities are lessened with age. As a matter of fact, however, comparison of the present results of the treatment of cancer in patients who are seen within any reasonable time after the onset of symptoms with the results of treatment of other serious diseases twenty or thirty or more years back is not discouraging.

In those years great strides have been made in the treatment and prevention of many of the formerly most deadly diseases, such as tuberculosis, typhoid fever, diphtheria, scarlet fever, and measles.

No such great improvement has been made in the results of cancer treatment; there has been no dramatic change. No new methods have been introduced since radiation therapy was adopted. Nevertheless, there can be no question that results are today better than in the past.

In 1941 the American College of Surgeons announced the registration up to that time of 38,818 five-year cancer cures, including

	Number of Cases
Cancer of the bladder	1,025
Cancer of the bone	361
Cancer of the breast	10,729
Cancer of the larynx	357
Cancer of the ovary	767
Cancer of the rectum, colon, appendix	3,250
Cancer of the skin	2,383
Cancer of the stomach	1,279
Cancer of the thyroid	582
Cancer of the uterus-cervix	8,925
or fundus	1,920
Cancer of other sites	7,240
Total	38,818

Certainly these results must be considered encouraging, yet we hope for still better showings. The chief stumbling block is that we do not get the cases early. The ideal time for treatment is when there is still a clinical doubt as to the nature of the growth.

## HEALTH SERVICE ESTABLISHES TUBERCULOSIS CONTROL DIVISION

A Tuberculosis Control Division has been established in the U.S. Public Health Service, Federal Security Agency, to wage the nation's \$10,000,000 war against tuberculosis, Surgeon General Thomas Parran announced on July 10.

Dr. Herman E. Hilleboe, who has been in charge of Public Health Service tuberculosis control activities since 1942, was named chief of the new Tuberculosis Control Division.

The division was established under authority given to the Surgeon General by the recent Public Health Service Act of 1944. Dr. Parran's order was approved by Paul V. McNutt, Federal Security Administrator. The Tuberculosis Control Division will be within the Public Health Service's Bureau of State Services, of which Dr. L. R. Thompson is head.

When Congress appropriates the authorized funds, the new Public Health Service division will be able to conduct a program for tuberculosis control comparable to the national program of the Venereal Disease Division, Dr. Parran said.

Functions of the new Tuberculosis Control Division include:

1. Developing more effective measures for the prevention, treatment, and control of tuberculosis.
2. Assisting states, counties, health districts, and other political subdivisions of the states in establishing and maintaining adequate measures for

the prevention, treatment, and control of tuberculosis.

3. Preventing and controlling the spread of tuberculosis in interstate traffic, and any other activities with respect to the prevention, treatment, and control of tuberculosis that may be authorized to be performed by the Public Health Service.

Dr. Hilleboe, born in Westhope, North Dakota, studied at the University of Minnesota Medical School, where he received his Bachelor of Science and medical degrees, and at the Johns Hopkins School of Hygiene and Public Health, where he received a Master of Public Health degree. He is a member of a number of medical societies and health organizations, including the National Tuberculosis Association, on whose board of directors and medical research council he serves.

Dr. Hilleboe was appointed to the Public Health Service as a passed assistant surgeon in the regular Commissioned Corps in 1939. He made special studies of tuberculosis control for the Public Health Service in the Scandinavian countries, France, and England, in 1939. Upon his return from Europe he was made chief of the Medical Unit of the Minnesota Division of Social Welfare, in which capacity he served until 1942, when he was appointed medical officer in charge of the Public Health Service Tuberculosis Control Section, States Relations Division. He became senior surgeon in 1943.

# OPHTHALMOSCOPIC SIGNS OF TERMINAL HYPERTENSION

ARTHUR J. BEDELL, M.D., F.A.C.S., Albany

**T**HIS communication is the result of questions asked by practicing physicians who, when seeking enlightenment, complain that the conclusions of ophthalmologists often leave them not only in doubt as to the findings, but also in a state of confusion regarding prognosis.

It may be presumed that hypertension without demonstrable kidney change is only an early stage of the general state which produces cardiac, kidney, and circulatory signs. It is conceded that therapeutic and hygienic measures may delay the end, that complications caused by increased changes in organs like the kidney or heart may alter the course of the disease, and that excessive localizations may bring death before the entire body becomes equally involved.

It is further agreed that hypertension may be present for many years without impairment of the visual function; that increased pressure is tolerated better by women than by men; and that some physiologic processes, such as, for instance, pregnancy, may inaugurate it. Hypertension is so common, affects so many people, is so influenced by the mental and physical impacts of life, excessive indulgence in alcohol and tobacco, and heredity, that physicians and patients are more conscious of it than ever before.

There may be a long period between the onset and the discovery of the increased blood pressure. The alert physician learns to recognize spasm of the retinal arteries, and appreciates the fact that the sudden loss of vision caused by embolism and endarteritis of the central retinal artery or the closure of the corresponding vein may be the first evidence of the vascular state. Parenthetically, it must be stated that all vessel closures are not caused by hypertension. The competent physician always uses the ophthalmoscope to correlate his general findings.

From the records of hundreds of patients suffering from hyperpiesia a few have been selected to emphasize the importance of recognizing early deviations from the normal fundus and to understand their significance in terms of life expectancy.

The special group of hypertensives which is the subject of this discussion cannot be divided into sharply demarcated classes because there is no definite time or fundus change which specifies the day of transition from a benign state to a malignant one, although there are distinctive patterns which assist in the classification.

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, May 10, 1944

The fundus changes in terminal hypertension have been selected for this demonstration, and in an arbitrary, but clinically practical, way the cases are segregated into three classes, and, as will be noted, the time of death and duration of the period of observation form the basis of the separation into cases which have been seen for years, patients who were seen only in consultation or for a short time, and those with papilledema. Caution must be observed in placing cases in the papilledema class, because edema is found in all advanced hypertensives and there are numerous causes of choked disk.

## Cases Under Observation for a Long Time

The first subdivision includes patients who have been under observation for years, or months, and in which the fundus picture suggests impending death, although it may not occur for months. The accompanying physical and mental deteriorations may, but often do not develop apace with the ophthalmoscopic danger signs.

The review of a short synopsis of the history and physical findings of several patients will serve to illustrate the necessity of careful and complete fundus descriptions.

*Case 1.*—H. S. had been under observation for thirty-one years when seen on June 22, 1939, when he was 66 years old; the disk was clearly outlined; the arteries were slightly irregular in caliber. There was an isolated increased vessel reflex. His systolic pressure was 230 and he was advised to reduce his mental activities. This he failed to do, and when seen May 16, 1941, fresh striate hemorrhages were found on the disk with definite retinal edema, and his systolic pressure was 210. Even then he failed to follow the advice to lessen his work. He died three months later with cardiac failure.

*Case 2.*—R. M., a navy medical officer who had been under observation for a great many years, was examined October 21, 1940. His vision was corrected to 6/6. The disk was clearly outlined; the veins were normal in distribution and size. The arteries were smaller than normal. There were, however, no irregularities of lumen and there was no increase in the artery reflex. His systolic pressure was 212. He was not conscious of any physical restrictions.

On August 30, 1943, his pressure was 190; his vision was 6/6 with correction. The changes in the fundus—several superficial retinal hemorrhages with gross changes in the artery lumen and retinal edema—were sufficient to order an immediate and complete rest.

The patient had a cardiac attack five weeks later and died.

*Case 3.*—L. F., a 55-year-old dentist, was ex-

amed five months before his death. There were a few soft, white, cotton-wool exudates and the retinal arteries were of very irregular caliber. Three months later the previous exudates had disappeared but new spots had developed. There was definite retinal edema and superficial flame-shaped hemorrhages.

Two months later the retinal edema was still greater, but the hemorrhages and exudates had been absorbed. He died in a few days.

This is an illustrative case of progressive hypertension with excessive pressure and interference with cerebral circulation which led to mental derangement. During the entire period of observation he had only slight and transitory fundus changes which were, however, sufficient to warrant a serious prognosis. His systolic blood pressure was 240 and his vision was never less than 6/6 in each eye.

*Case 4.*—A. J., a physician who had been seen for many years without any fundus or constitutional signs of hyperpiesia, was examined May 14, 1942, because he had had a transitory right facial paralysis. The blood pressure was found to be 210/118.

His corrected vision was 6/6. The right fundus was negative except for two things which were significant: one, a small circular, granular, deep retinal hemorrhage and the other the reduced size of the arteries with increased reflex and irregularities of the lumen. In the left eye the vision was 6/6. The retinal vessels were very slightly constricted. There were no hemorrhages or exudates.

His fundus changes were slight but sufficient to lead to the advice to slow down. Like the majority of active medical practitioners, he could not lessen his burden of anxiety over sick patients, and as a result of the progressively increasing tension he died less than two years later at the age of 55.

*Case 5.*—G. H., when he was 44 years old, had a thrombosis of the left superior temporal retinal vein. The vision of the right eye was corrected to 6/6 and he was comfortable until twelve years later, when he reported for a routine examination.

Vision of the right eye was 6/6. There were several superficial retinal hemorrhages and definite retinal edema with an acute right-angle crossing of the inferior artery over the inferior vein. The disk was edematous with a decidedly uneven surface, most prominent on the nasal side. There were several superficial hemorrhages and a few deep granular ones. The artery reflex was accentuated. The systolic blood pressure was 202. He was advised to work less.

Eighteen months later, his systolic pressure was 250 and, although he felt well and presented no gross evidence of physical distress, his fundus changes were so marked that an urgent message was sent to his family explaining his critical condition. The vision with glasses was 6/6. The fundus was congested. The edema was not only greater in the nervehead but also throughout the entire fundus. Numerous large blood streaks were present and several fine, yellow dots were between the disk and the macula. He died six months later. This case was of interest because during the years' observation there was no measurable change in the course of the retinal arteries.

## Patients Seen for a Short Time

The second subdivision includes patients who, although seen for a short time, presented significant fundus signs.

*Case 6.*—In contrast to the patients who, for one reason or another, fail to relax, we record the history of A. F., who was first seen when he was 71 years old because he felt the need of new glasses. The vision of the right eye, with correction, was 6/6. The nasal side of the disk was edematous, the caliber of the arteries was slightly uneven, but the veins were not compressed by them; and several small, granular hemorrhages were the signs of circulatory disturbance.

The vision of the left eye was 6/30. The disk was clearly outlined; the nasal side was slightly edematous. The arteries were unequal in lumen and many hemorrhages were scattered over the retina. There was a circumscribed macular edema.

The patient was amenable to suggestion and, when told that his blood pressure (232 systolic) was high and that relaxation was necessary, he stopped work, went to a warm climate, and lived comfortably for twenty-two months. No claim is made that rest is the only requisite for prolonging the life of those afflicted with hypertension, but I am convinced that it is of value.

*Case 7.*—C. C., a 44-year-old man who complained of drowsiness and occipital headache, presented the characteristic signs of advanced hypertension as seen in the stout, red-faced individual.

In the right eye the fundus was congested, with broad veins and narrow arteries. The nasal half of the disk was edematous and over the entire disk surface there were fine vessels. The retina was edematous with several thin, cotton-wool exudates.

The left eye presented greater changes. The fundus was dark red, the veins were more dilated than in the right eye, and the arteries were not only narrow but in places markedly contracted, while in others the wall was white. There were many large granular, deep retinal hemorrhages and several small cotton-wool exudates. On the uneven surface of the disk there were delicate lines of fresh blood and an increase in the number of blood vessels.

This was malignant hypertension as photographed thirty days before his death. His pressure varied from 252/156 to 210/125. He died in uremic coma. His fundi had never been examined before.

*Case 8.*—The next case was that of a young man who died when he was 26 years old. Two years before death his fundi were negative. The disks were round and clear with normal vessels and retina and he was in good health. He was not seen again until twenty-five months later. The entire retina in each eye was edematous, with great masses of exudate, soft white clouds, and harder-looking yellow specks. The veins were of normal size and showed neither increased tortuosity nor compression changes. The arteries were very narrow and frequently hidden in the overlying retina. Two kinds of hemorrhage were widely dispersed—superficial streaks and deep granular round spots.

The swelling of the retina pushed the vessels up-

ward and made them appear displaced nasally. His pressure was 235/165, and seven weeks later he died.

### Patients with Papilledema

The presence of papilledema has been made the diagnostic criterion for inclusion in the third subdivision. This group is of the greatest clinical interest, for we must decide whether the hypertension is the sole cause, whether the papilledema is the result of cerebral pressure, or whether hyperpiesia and brain tumor are both present. To arrive at the correct diagnosis is not always easy and at times it is very difficult.

**Case 9.**—Mrs. G., 44 years of age, came for glasses. Her vision was failing and she had never had an eye examination. Three weeks before consultation she had had a pressure back of her head and over the base of her nose. The right eye felt sore and she had severe, generalized headache.

The vision of her right eye was 6/18. The disk was indistinctly outlined, with a pale blue edema partially concealing the vessel extending over it. The swelling was one diopter. The entire retina was edematous and the arteries were of unequal caliber.

The vision of the left eye was 6/15. There was much greater edema, the disk was elevated 3 diopters, with the same pale blue color as that noted in the right. The surface of the disk was uneven and the center was a pale pink because several fine vessels were dilated. The arteries were narrow—in places mere threads. The veins were not distended, but along the superior temporal branch there was a fresh hemorrhage a disk diameter in length and one-third as wide.

Her blood pressure was 220/140. Her physician was told immediately of the seriousness of the condition. She died five days later.

**Case 10.**—When Mrs. D., 41 years of age, was examined because of her poor sight she had only faint light perception. Both nerveheads were immensely swollen—4 diopters—with a yellow, waxen color, retained central excavation, full major veins with very few branches, and very small attenuated arteries. There were no retinal hemorrhages or

edema  
blood

cases. She was 200/100, I advised her to see Dr. Gilbert Horrax. He did a ventriculogram and could find no tumor. She is still alive, but her condition is so critical that she is included in the terminal

**Case 11.**—And, finally, to illustrate combined tumor and hypertension, the case of a 60-year-old woman who was first seen seven years ago is cited. She had no headache and her only complaint was failing eyesight.

The vision of the right eye was 6/400. The disk was elevated 4 diopters, the surface was rounded and vascular, and the central excavation was retained. The retinal arteries were small and compressed the distended veins where they passed over them. There was a partial macular star of exudate.

The vision of the left eye was 6/60. The disk edema was greater—6 diopters; the nervehead was rounded and so prominent that the thick nasal side partially overlapped the still present central excavation. There were several fine hemorrhages on the disk and a few larger ones in the retina to the nasal side. The veins were only moderately full; the arteries were small but not as narrow as those in the right.

The field of vision was of the hemiopic type. Examination showed that she was deaf in her left ear. Her blood pressure ranged from 200 to 170. She was sent to Dr. Horrax, who removed a large left acoustic neuroma.

Her recovery has been gratifying. The disks are flat, and although there is some secondary optic atrophy and a perceptible narrowing of the retinal arteries, she is comfortable and her blood pressure is stabilized at 180.

In a short paper of this nature the greatest difficulty is in keeping the discussion confined to the one phase of the immense problem of hypertension—what fundus signs suggest a serious outcome. A thoughtful perusal will stimulate interest and eventually more patients will receive better advice and perhaps more of them will follow it.

### Summary

This clinical approach to the prognosis of hypertension, as evaluated by one or more ophthalmoscopic examinations, is presented because it has been found serviceable.

### Conclusions

Patients are separated into those who come early, when there is still time to give advice as to how they should live; those who are seen when the finger of death points to them and only by extremely good care can the hand of fate be turned aside even for a short period; and, finally, those who are in the embrace of death and no earthly force can release them.

It is unwise to consider papilledema, or choked disk, as caused by hypertension until brain tumor has been excluded by exhaustive tests.

The object of this demonstration is to describe some of the changes which take place in the fundi of patients suffering from advanced hypertension and to show how their recognition aids in arriving at a correct prognosis as to the probable duration of life.

### Discussion

Dr. Searle B. Marlow, *Syracuse*.—Dr. Bedell has graphically presented the clinical and ophthalmoscopic picture of hypertension in its terminal stages. There should be no difficulty in the recognition of the condition nor hesitancy in diagnosis. Differential diagnosis, as Dr. Bedell has been careful to point out, may sometimes be difficult. An accurate

diagnosis is essential, especially from the point of view of prognosis, for in cases of thrombosis it is probably true that these patients live longer. It must be conceded that if treatment, medical or surgical, is to be of benefit this condition must be recognized long before the changes described by Dr. Bedell are in evidence. The part played by the ophthalmologist in this connection, is of no small importance.

The frequency of the occurrence of these changes in office patients is apparent from a review of 2,000 consecutive new office cases of all ages. Among the records 142 were found on which there was a definite note concerning the state of the retinal vessels. No doubt this number is low, as many fundi were probably recorded as normal if the vascular changes did not seem excessive in view of the patient's age. In only twenty-four instances was there a history of hypertension according to the patient's statement or that of the physician in charge. There were five patients with a history of hypertension who showed no ophthalmoscopic signs. Among these 142 patients there were only 9 with retinal hemorrhages, 3 of these having, in addition, exudates, so that the advanced changes described by Dr. Bedell may be said to have occurred only three times in 2,000 cases.

There were, however, 9 cases of thrombosis and 1 of homonymous hemianopia. These figures indicate that, whereas the instances of the advanced changes are low, the earlier changes are much more frequently seen. One can only agree with Dr. Bedell that the ophthalmologist has a duty in advising these patients to seek medical care as well as to inform their physician of the conditions found.

It is impossible to review all the etiologic theories in regard to hypertension and the pros and cons of treatment. It is well, however, to remember that the retinal changes are not the only ophthalmologic complications to be found in this disease. These observations are based on office patients. Undoubtedly a review of a similar number of hospital patients (they are sicker) would produce a much higher incidence of advanced changes and a review of a selected group of cases of hypertension a still higher.

The whole point of this discussion is that, whereas few advanced cases may be seen, the opportunities for help to the patient and his physician in the early stages are many.

Dr. Morris H. Newton, *Little Falls*.—Four or five years ago I became slightly interested in hypno-

sis in relation to speech defects and hysteria. The chief conclusion of my limited investigation was the fact that one who undergoes hypnosis successfully appreciates the true meaning of the word relaxation. Some of our patients drive themselves all day and, even though they assume a recumbent position at night, carry through a muscle tone and mental anxiety which, I believe, if it is not the cause of hypertension, is a definite aggravating factor.

I might mention in passing that my interest in hypnosis lagged after a patient with intermittent bilateral vertical nystagmus with no visible pathology, who seemed to improve for a long period after hypnosis later was found to have and was operated upon for a tumor of the occipital region.

On May 4, I saw Mrs. M. N., aged 45, an apparently healthy woman whose vision was corrected to normal in each eye and whose blood pressure was 170/90. She had been told that this was not alarmingly high and she continued her daily routine, plus extra duties, in an endeavor to forget the dangers to which her son is being subjected on the high seas. Her retinas showed definite blood vessel changes—depressions at the right-angled crossings and minute hemorrhages in the right disc. This woman is intelligent and, I believe, will cooperate fully in the regulation of a more relaxed life.

A woman, F. P., aged 49, who has been in our employ as a domestic for nine years, was an exceptional worker. She drove herself from ten to twelve hours daily at our house besides caring for her husband and two children at her own home. Four years ago it was discovered, following a cerebral accident, that her blood pressure was 220/140, with vision correcting to normal. Two and a half years ago she had a gross hemorrhage in the right eye following a hysterectomy. The fundi at that time showed a malignant hypertension and I told the family that, unless she lived a more relaxed life, her life span would be less than two years. She is still active in her home and occasionally does light work outside.

I am of the opinion that most patients and their physicians consider blood pressure from a purely numerical standpoint and are not made conscious of the pathology and causative factors behind it and the benefits of mental and physical relaxation.

Dr. Bedell's paper this time, as always, stimulates my interest in fundus pathology through his concise, practical, and picturesque presentation of the subject.

## NATIONAL FOUNDATION FOR INFANTILE PARALYSIS OFFERS SCHOLARSHIPS

The National Foundation for Infantile Paralysis has made grants to provide scholarships in physical therapy and orthopaedic nursing for doctors, nurses, and physical therapy technicians. The amount of the scholarship is determined on an individual basis. The training courses are for a period of one year.

The American Physiotherapy Foundation is administering the scholarships for physical therapy technicians, and the National Organization for

Public Health Nursing, Inc., and the National League of Nursing Education are administering the orthopaedic nursing scholarships. In addition to these projects, the National Foundation for Infantile Paralysis has established seven training centers which provide short-term courses teaching the changes introduced in the last few years in the treatment of infantile paralysis, including instruction in the Kenny method.

# PENTOTHAL SODIUM ANESTHESIA IN SHOCK AND HEMORRHAGE

CHARLES K. ELDER, Capt (MC), Atlantic City, New Jersey

**D**ESPITE the plethora of material that has been written on the uses of sodium pentothal there exists an unsolved problem. The question as to whether it should be employed for anesthesia in patients depressed from the effects of shock and hemorrhage remains unanswered.

Review of the recent reports on the use of this agent in military casualties reveals conflicting opinions. There exists an open question as to whether pentothal sodium should ever be employed in the anesthesia of severe casualties. As with all problems semi-theoretical, the solution lies in sufficient critical observation and analysis of practical results.

Under normal circumstances one principle should remain inviolable: that a state of circulatory insufficiency resulting from either shock or hemorrhage must be restored to normalcy before any surgical or anesthetic procedure is attempted. In military exigencies it may not always be possible to apply this time- and labor-consuming principle. Hematocrit studies, serial blood studies, and plasma protein determinations will not always be available. Inevitably, cases will be presented for emergency surgery that are in the occult stages of shock and hemorrhage. Anesthetic and surgical trauma are disastrous in this type of case.

Several properties of pentothal sodium make it attractive for use in military field anesthesia. Transportation difficulties are minimized. It is nonflammable. A minimum of apparatus is required. The ease of induction, maintenance, and the uneventfulness of recovery in the good-risk patient lends support to the somewhat prevalent impression that it can be administered without hazard.

A brief résumé of the essential physiologic changes occurring in shock and hemorrhage, and of the characteristics of pentothal sodium, will be presented here. The method of administration of pentothal sodium will be considered. Some refinements in the control of anesthetic levels are suggested. These facts may prove superfluous to the professional anesthetist. They will prove valuable to medical officers who have had a limited experience with anesthetic problems.

## Pharmacologic and Toxic Characteristics of Pentothal Sodium

The outstanding characteristic of the barbiturates administered in large anesthetic doses

is depression. The vital centers effected most severely are the respiratory center, the vasomotor center, and the carotid sinus mechanism. Blood pressure is decreased with large anesthetic doses due to the direct action of the drug on the myocardium, and to the direct action of the drug on the vasomotor center with peripheral vasodilatation.<sup>1</sup> The result of these changes is stagnant anoxia due to decreased volume flow. The depression of the respiratory center results in a decrease in minute volume exchange. The decrease in ventilation favors the development of an anoxic anoxia. The ultimate result of both the circulatory and respiratory depression is deficient tissue oxygenation.

Of considerable importance is the fact that the laryngeal and pharyngeal reflexes remain active in all but the profound levels of pentothal sodium anesthesia. Pentothal sodium is a bronchoconstrictor.<sup>2</sup> Under certain conditions these factors can become a major hazard, causing a serious or complete reduction in respiratory exchange. Excessive concentrations of barbiturates may dilate and injure capillary beds to such an extent that shock ensues.<sup>3</sup>

## Physiology of Shock and Hemorrhage

Omitting the controversial aspects of surgical shock and hemorrhage, there remain several undisputed physiologic facts.

Circulatory insufficiency and tissue anoxia are a major factor in the mechanics of early shock and in the advanced stages of hemorrhage. Endothelial damage (the end result of tissue anoxia) produces the ultimate pathologic changes of shock and probably of hemorrhage.<sup>4</sup> Sustained hypotension from any cause creates a condition of circulatory insufficiency that becomes progressive. The condition acquires a self-perpetuating quality having the features of a vicious circle.<sup>5</sup> Anoxia will cause circulatory deficiency and circulatory deficiency will cause anoxia. The vicious circle set up is aptly termed the cycle of death.<sup>6</sup>

## Correlation of Drug Characteristics and the Physiology of Shock and Hemorrhage

In correlating the reactions of the barbiturates with the physiologic changes occurring in shock and hemorrhage, several serious incompatibilities appear.

The depression of minute volume exchange resulting from deep pentothal sodium anesthesia results in an anoxic anoxia. As an-

oxemia already exists in shock and hemorrhage, reduction in minute volume exchange is ill-advised. The depression of the vasomotor center, the peripheral vasodilatation, and the myocardial depression resulting from large anesthetic doses of pentothal sodium are directly antagonistic to the compensatory reactions that the organism attempts to effect in shock and hemorrhage. Further insufficiency of circulatory volume and tissue anoxia result. The sequence of anoxia-endothelial damage is reversible to a point, but beyond that point the damage becomes irreversible, and death is inevitable.

### Method of Administration

It seems highly desirable that if pentothal sodium is selected for anesthesia in patients handicapped by shock and hemorrhage, more exact control of the anesthetic level be exercised. Avoidance of profound anesthesia and as drastic a reduction in total drug dosage as possible are mandatory. Review of the literature and observation of methods of controlling anesthesia with pentothal sodium leave the impression that the concept of the exact signs of anesthetic levels is somewhat vague.

Demonstration of the exact signs of anesthetic level referred to necessitates the use of a 2 per cent solution of the drug. Administration must proceed in intermittent doses of 2 to 3 cc. Sufficient time (fifteen to thirty seconds) must elapse

between injections for the maximal effect of each dose to become evident. Patients depressed by shock and hemorrhage are rapidly and deeply anesthetized by extremely small amounts of any anesthetic agent.

Some form of a mechanical syringe holder is a convenience, as it allows the anesthetist to stand at the patient's head and observe the progress of anesthesia minutely. Some visible indicator of respiratory exchange is desirable.

### Signs of Anesthesia

The slow induction of anesthesia as outlined enables the anesthetist to utilize as a guide most of the classical signs of the various anesthetic levels. (The pupillary changes are the exception, as they are of no value until profound anesthesia occurs.) The signs described apply to anesthesia in good-risk as well as in handicapped patients.

A modification of Guedel's<sup>6</sup> chart (Fig. 1\*) is employed to illustrate the anesthetic signs. Emphasis is placed on certain of the signs as more applicable to pentothal sodium anesthesia.

The arrival of the patient in first and second plane of pentothal sodium anesthesia is signified by the following signs:

1. In mid-first-plane anesthesia the eyeball activity becomes progressively less, the eyeballs tending to rest in eccentric positions. The

\* Reprinted with permission from the Macmillan Co.

muscle tone of the upper lid becomes progressively diminished, although the wink reflex at this point may not be totally abolished. Some residual muscle tone may be demonstrated in the upper lid by flicking the patient's lid upward with the ball of the index finger. This discrimination is a fine one, requiring a practiced appreciation of minute differences in muscle tone. The breathing tends to be regular and of fair volume at this point.

2 As anesthesia progresses into second plane the eyeball activity disappears. The eyeballs come to rest exactly in a centric midline position. The muscle tone of the upper lid disappears completely, causing the palpebral fissure to widen spontaneously. Flicking the upper lid gives the impression of complete flaccidity. The breathing remains regular, and may or may not diminish in volume at this point. As the anesthesia progresses into lower second plane and on to third plane, there is a distinct decrease in amplitude of respiration, and an increase in rate.

3 The pupillary signs are not of any value up to and including second plane anesthesia. The pupils do not dilate until a profound depth of anesthetic level is reached. This dilatation may be anoxic in origin.

### Clinical Application

Reflex response to skin trauma is ordinarily abolished in the upper half of the first plane. It follows that it is necessary to produce anesthesia to a depth slightly exceeding this level for even minor surgery. Skin trauma inflicted at an anesthetic level more superficial than lower first plane results in reflex movement of the patient. Premature surgical trauma frequently results in laryngospasm with embarrassment of respiratory exchange.

It is practical to induce anesthesia employing pentothal sodium, limiting the depth of anes-

thesia to lower first plane or upper second plane. It is possible to maintain an even course of anesthesia at either of these levels. The closest attention to the signs described is required, in order to maintain a level of anesthesia which will not regress into upper first plane, or progress into lower second plane and beyond.

### Summary and Conclusions

1 The relevant changes of physiology in shock and hemorrhage have been described.

2 The major pharmacologic characteristics of the barbiturates in general, and of pentothal sodium in particular, have been enumerated.

3 The antagonistic relationship between the reactions of pentothal sodium and the physiology of shock and hemorrhage have been discussed.

4 A method of accurately determining anesthetic levels in pentothal sodium anesthesia has been presented.

5 Pentothal sodium is not considered to be the anesthetic agent of choice for military casualties, when shock or hemorrhage exists.

6 Shock and the effects of hemorrhage must be corrected prior to any surgical or anesthetic procedure.

7 Should pentothal sodium be administered in such a case, meticulous care must be exercised to avoid profound anesthesia.

### "PATENT MEDICINE" BALLYHOO ON THE RADIO

Although many leading publications of the country have made a serious effort to eliminate the worst of the "patent medicines" from their advertising pages, numerous radio stations remain notoriously backward in this respect. Hour after hour, day after day, loudspeakers of radios blare forth outrageous claims for some no-trum or "patented" home remedy. The "patent" remedies advertised range from those that may be positively harmful to those that are merely grossly overpriced in relation to their value. Even these, however, tend to delay the use of dependable foods or services and initiate the expenditure of funds that might better be applied to securing scientific diagnosis and treatment. Recently newspapers as

widely different as the *Chicago Tribune* and *PM* have almost simultaneously exposed some of the most notorious of the "patent medicines." But newspapers alone cannot solve this problem. The situation requires the housecleaning efforts of the radio industry itself and the more active interest of those in Trade and Professional Associations with responsibility in this regard.

The interests which exploit the sick through "patent medicine" advertising on the radio should not be allowed to tamper longer with the health and pocketbooks of the American people.—J. A. M. A., May 13, 1944.

## CONFERENCES ON THERAPY

THESE are stenographic reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with collaboration of other departments and institutions. The questions and discussions involve participation by members of the staff of the college and hospital, students, and visitors. The next report will appear in the September 1 issue and will concern "Use of Sedatives and Narcotics."

### Management of Disorders of the Thyroid: III. Cardiovascular Disturbances

DR. McKEEN CATTELL: Not infrequently the hour has proved too short to cover completely the topic assigned, and that was the case with the two conferences on the diseases of the thyroid. We thought it would be worth while this morning to discuss further a special aspect of this problem; that is, the treatment of the cardiovascular complications of thyroid disease. Dr. Gold, will you open the discussion?

DR. HARRY GOLD: Let me state at the outset that one should distinguish between cardiovascular complications and cardiovascular manifestations of thyroid disease.

A patient with Graves' disease may be subject to rheumatic heart disease, arteriosclerotic disease, or some other form of heart disease, and in that case we have one disease complicating the problems of the other, but I think it is intended to relate the discussion today not to that group, but rather to those disorders of the heart which occur as the direct result of the thyroid disturbance. The designation, cardiovascular complications of thyroid disease, is not strictly accurate as applied to this group. They should be referred to as the cardiovascular manifestations of thyroid disease. Cardiac disturbances may, indeed, be the dominant manifestations of thyroid disease in some cases.

These disorders are quite common. The heart is often involved in thyroid disease. Rapid heart action occurs in the vast majority—not in all, but in most of the cases. The cardiac difficulties present pressing problems, I should say, in about one-quarter of all the cases, perhaps even more. In many cases the heart presents the most serious aspects of Graves' disease. In a small number of patients—I am not sure how large that number is—the cardiac disturbances are the only manifestations, at least for a period—sometimes a period of years—after which the true nature of the cardiac disturbance reveals itself as one which has its basis in so-called "masked hyperthyroidism."

The more common disorders are sinus tachycardia, ectopic auricular tachycardia, auricular

fibrillation, and congestive failure. Some patients have more than one type of abnormal rhythm. Auricular flutter is a less common accompaniment. Auriculoventricular block is also uncommon.

The chief nonspecific agents which are effective in the control of these disorders are quinidine, digitalis, mechoyl, and iodine. Now we must add thiouracil. Thyroidectomy cures in the vast majority of cases of Graves' disease. The administration of thyroid materials controls them in the occasional case in which the underlying cause is hypothyroidism or myxedema.

There are certain special features about the cardiovascular disorders of Graves' disease which have a bearing on the choice of treatment, and also on the outcome. The first is that the disorders of the heart in Graves' disease are likely to be paroxysmal or transient. The auricular fibrillation caused by thyrotoxicosis usually disappears within a few days after thyroidectomy.

The congestive heart failure which is caused by toxic thyroid disease is also apt to be transient. It is, as a matter of fact, one of the striking features of the history of heart failure in the thyrotoxic patient, namely, that he, or more often she, has had repeated attacks of failure without the customary precipitating causes, such as effort or infection, and that there have been long periods of remission. Such a history of recurring attacks of heart failure without the usual causative factors is strongly suggestive of thyrotoxic heart failure.

It is also noteworthy that the heart disorders of thyroid disease are reversible to a very high degree. This also applies to the enlargement of the heart in thyroid disease. A large proportion of the cases, particularly the more severe ones, have some enlargement—it is usually mainly a dilatation—and with the cure of the thyrotoxic disease the heart usually returns to its normal size. Even in cases of heart failure with congestion of the most extreme grades, in which patients seem in extremis, and fail to respond to the ordinary forms of treatment, the control of the thyrotoxic disease by thyroidectomy often results in a cure

of the heart condition that is to all intents and purposes complete. Such complete cure is very rarely encountered in any other forms of heart disease with failure.

The third general characteristic of this group is that thyrotoxic heart disorders are in general more resistant to the common cardiac drugs than similar disorders of other cause. The distinction is not absolute. There are a great many cases of auricular fibrillation due to thyrotoxic disease in which the heart can be slowed readily with the usual doses of digitalis, and there are many cases of heart failure due to thyrotoxic disease which can be satisfactorily controlled with the usual doses of digitalis, but there is among them, on the whole, a larger number of patients who do not respond satisfactorily even to the largest doses than among individuals with heart disease of other cause.

These, then, are the three outstanding characteristics of the thyrotoxic heart: the transient disorder, the reversibility of even very severe forms of disorder (failure and enlargement), and the tendency to show a greater resistance to the usual therapeutic measures.

The rapid heart rate of Graves' disease is usually a sinus tachycardia. When it is of the order of 110 or 120 a minute, it does not require treatment. There are individuals, however, in whom the disease becomes very active and the rate speeds up to 200 or so a minute, much too fast for an efficient circulation. It is fortunate that this does not happen very often, because we have no direct means of slowing the sinus tachycardia of thyrotoxicosis. Digitalis is of no value. It is often given for sinus tachycardia and in large amounts. All that results after enough of it is poisoning. The heart rate remains fast. Nor does quinidine slow this type of tachycardia. The only way to slow the sinus tachycardia of thyrotoxic individuals is to control the thyrotoxicosis. The measures are the administration of iodine and/or thyroidectomy. In the preparation for thyroidectomy the heart will slow in a striking manner after suitable doses of iodine. The effect of this treatment is usually temporary. I think it should be regarded essentially as a pre-operative measure rather than as a means of maintaining the heartbeat at a slow rate in a thyrotoxic patient. It is rarely possible to keep it slow with iodine alone over more than periods of weeks.

The dose of iodine necessary for that purpose is not very large—not very large as doses of iodine are considered in therapeutics—but it really represents a great deal of iodine. One teaspoonful of the syrup of hydriodic acid daily will slow the heart rate in these cases from 120 or 130 a minute way down to normal levels within a

period of about a week or ten days. A teaspoonful of hydriodic acid is not usually considered a large dose, but again, in terms of iodine content, it is a good deal. It contains about 50 mg. of iodine, which represents about twice the iodine present in the body of a normal individual.

Regarding the treatment of auricular fibrillation in thyrotoxic disease, the workers in this field seem to be in agreement with respect to only one point, namely, that the fibrillation should be abolished. Some wait for spontaneous cessation and others use drugs to abolish it, but there is no consensus as to when the fibrillation should be abolished, and as to what should be used for the purpose. Some depend upon digitalis, others use quinidine.

There seems to be a belief that quinidine ought not to be given in auricular fibrillation of the thyrotoxic patients prior to operation, and the advice seems to be fairly general, in writings on the subject, to use quinidine after the operation, if within a certain period of time the fibrillation does not cease spontaneously. Well now, how long after? One writer says within two days, and another advises to wait at least three months before quinidine is given.

I am not sure what the reason is for the objection to the use of quinidine prior to operation to abolish an attack of auricular fibrillation in a thyrotoxic individual. I would like to recommend that an attempt be made in every patient who develops auricular fibrillation as the result of thyrotoxic disease to abolish the fibrillation by quinidine, provided the case is without the usual contraindications to the use of quinidine, or presents factors which make digitalis more desirable, namely, a complicating mitral disease of long standing, or an auricular fibrillation which may have been going on for many months, or congestive heart failure. Perhaps we can have some discussion of this point. I know of the argument that quinidine prior to operation will fail to abolish the fibrillation. I do not wonder at the failures. The doses commonly used are too small. The way to use quinidine to abolish auricular fibrillation in these cases is to give 10 grains of the sulfate every two hours until the normal rhythm is established, or until the minor toxic symptoms preclude its further use.

The idea also seems to prevail that the thyrotoxic patient is more sensitive to the toxic effects of quinidine than the normal individual. I am inclined to doubt it. In the old Forchheimer treatment of Graves' disease quinine was given in very large doses, 2 to 6 Gm. a day, and it was considered characteristic of thyrotoxic patients that they were more tolerant to the toxic effects of quinine than normal persons.

If quinidine is not successful in abolishing the

auricular fibrillation and the rate is very rapid, digitalis may be used to slow the ventricular rate to as nearly normal levels as possible. Give the patient 1.25 mg. of digitoxin (Digitaline Nativelle) at one time. Within eight to ten hours the rate will slow, as a rule. The likelihood of toxic symptoms with this dose is practically nil. If it isn't enough, give a tablet or even two tablets of 0.2 mg. daily as necessary. If you use digitalis leaf, a daily dose of 6 grains for two or three days is likely to accomplish essentially the same result. A daily maintenance dose is, of course, necessary in every case.

Congestive heart failure of thyrotoxic disease requires the same treatment as heart failure under other conditions. Full digitalization comes first. If the failure symptoms do not subside with that treatment alone, 1 or 2 cc. of mercupurin or salyrgan with theophylline given intravenously every day will help a great deal. The administration of iodine will sometimes produce dramatic effects in these cases. The iodine may be given in the doses suggested before: a teaspoonful daily or twice daily of the syrup of hydriodic acid.

The only measure which insures a high proportion of cures in thyrotoxic disorders of the heart—one rarely speaks of cure of heart disease, but when the condition is due to thyroid disorders cure is common—is thyroidectomy. The medical treatment of the heart in thyrotoxic patients cannot stand up long by itself. It should be considered for the most part as pre- and post-operative treatment. Thiouracil may indeed now change the outlook for protracted control by medical treatment. We shall have to wait to see how that turns out.

DR CATTELL. Dr. Eggleston, will you continue the discussion from the standpoint of the patient with hypothyroid disease?

DR. CARY EGGLESTON: This is an aspect of thyroid disease which is not well established. There are many who feel that there is no such thing as the myxedema heart, as originally described a number of years ago by Zondek, in Germany, and supported in this country very largely by Fahr. On the other hand, there are many who do feel that there are relatively rare cases in which myxedema is largely responsible, possibly wholly so, for cardiac insufficiency. There is no satisfactory evidence as yet which permits us to say which of these two groups is correct. Personally I think the truth lies between them; that there are small numbers of patients with myxedema in whom there is evidence of cardiac failure and in whom adequate control of myxedema may relieve the cardiac failure.

It has been noted that in such patients who have had myxedema with symptoms of cardiac insufficiency who have come to autopsy there

has been a very high incidence of coronary arteriosclerosis, and there are many who feel that it is this process rather than the myxedema which is responsible for the cardiac manifestations.

A few years ago, as the result of the efforts to reduce basal metabolism as a therapeutic process in reducing the work of the heart, the Boston group operated upon a good many patients with heart disease—heart disease of the anginal type and heart disease of other types—causing a total ablation of the thyroid resulting in a myxedema and reducing the basal metabolism in general to levels below -25 per cent. This gave us an opportunity to observe the effects of induced hypothyroidism upon the heart. In few or no instances were there any apparent detrimental effects, and so far as effects were observed, they were largely beneficial or else of no significance.

The manifestations of hypothyroid disorders of the heart differ distinctly from the ones spoken of by Dr. Gold. It is true that tachycardia may appear. Usually it is concomitant with an associated heart failure. The rate is commonly slow in myxedema. Arrhythmias are occasionally observed. Ectopic premature beats, generally of the ventricular rather than of the auricular type, have been observed. However, the irritability of the myocardium is in general reduced in myxedema so that we are not greatly troubled with the problems of dealing with these functional disturbances of the cardiac mechanism. The usual picture is one of congestive failure.

Less usual is that of the anginal syndrome. Where the anginal syndrome is present in the myxedematous patient it is a reasonably sound assumption to presuppose that it is due to coronary arteriosclerosis and coronary insufficiency.

The temptation is to treat the myxedematous patient who has cardiac manifestations radically. This temptation must be checked, because these patients seem to be quite sensitive to harmful effects of the administration of thyroid. It has been the practice of some to give as much as 1 Gm. of thyroid (15 grains) per day in the beginning of therapy. This has resulted disastrously in the hands of some of those who have practiced this irrational form of therapy. I believe that one should, if he is faced with the necessity of controlling cardiac symptoms, begin with the administration of small doses of thyroid or of thyroxin, doses of thyroid extract of not more than 30, possibly 60 mg. per day, and gradually increase if the treatment is well borne. We have seen a few of these patients in the hospitals in whom we have been able to control the symptoms quite satisfactorily on this regimen and get them into a thyroid balance that was reasonably adequate. On the other hand, we have seen several patients whom we could not control adequately

because the administration of thyroid, even in much smaller amounts, very promptly induced symptoms of angina pectoris. The symptoms of angina pectoris, as far as the patient was concerned, were worse than his manifestations of myxedema.

The other methods for the control of congestive heart failure are as described by Dr Gold, particularly the use of digitalis, but in my experience they have been rather unsatisfactory. If the patients do not respond to thyroid administration, I think there is very little that can be done for them.

I do not want to leave the impression that the myxedema heart, so-called, is an important form of cardiovascular disease. In my experience it is rare and it is generally relatively unimportant and often adequately controlled by a particular control of the myxedema through the administration of small ascending doses of thyroid or thyroxine.

DR CATTELL. Before opening the subject for general discussion, I would like to ask Dr Shorr to comment on the presentations to which we have just listened.

DR EPHRAIM SHORR. I would like to discuss Dr Eggleston's remarks about the myxedema heart first. There are several points which have struck us in this syndrome. The first is the infrequency with which heart failure is encountered. When I think back on the last 15 or 20 patients that we admitted to the hospital I can recall none with heart failure. The unusually high incidence of coronary thrombosis is also noteworthy. Its distribution in the general population between women and men is about one to five, whereas in the myxedema group which is of course composed largely of women, in the last 15 cases I can recall at least 4 patients with coronary thrombosis after replacement therapy.

With respect to the dosage of thyroid, I was so glad that Dr Eggleston stressed the necessity for low or small doses. We are inclined to refuse to treat myxedema patients unless they are willing to come into the hospital. We generally use even smaller doses than you advocate. Dr Eggleston, and the size of the dose is dependent upon the cardiac difficulty. We are inclined to start with 8 mg daily and not increase it until the effect of the dose levels off. The initial increments of dosage are small, from 8 to 15 mg from 15 to 30 from 30 to 45. During this period we ask the patient to be up and around because the behavior in bed is no indication of how the patient is going to behave when up and around.

We generally take, if we can, about two months to bring such a patient to the optimum, and that optimum is not decided by any arbitrary standards of the level of the basal metabolism. It is

that state, whether it be with doses of 30 mg, or 60 mg, or 180 mg, in which the patient obtains relief from symptoms without cardiac distress.

Here is an excellent opportunity to take advantage of a natural state, which the Boston group has been producing by operation. The patient with myxedema has, in a sense, natural thyroidectomy. He can be regulated at the level at which he is comfortable, without previous surgery.

I do not have any doubt, Dr Eggleston, of the existence of the myxedema heart, in the sense that the heart rate is slow, the size is generally increased, the circulation is slow, the work of the heart is less, and the PR interval may be prolonged to as much as 0.54 seconds in some cases. With therapy all of these usually revert to normal.

I would like to discuss Dr Gold's reference to "masked" Graves' disease. We are too often inclined to look for the textbook picture of Graves' disease: exophthalmia, a rapid heart, a large mass in the neck. People in the older age group just do not have this typical form of Graves' disease. The erroneous impression has grown up from work in certain midwestern centers that in the older group we have two types of disease: toxic adenoma and Graves' disease, and that toxic adenoma is merely hyperthyroidism, while Graves' disease is something else. This notion, to my mind, is erroneous. Whenever we see a patient in the old age group who has cardiac disease which does not respond as it should and with no obvious reason for it, we should suspect Graves' disease, regardless of the presence or absence of the so-called typical picture of Graves' disease.

DR EUGENE F. DUBOIS. Dr Evans and Dr Stewart have been doing a great deal of work on the heart in Graves' disease and myxedema. Could we have some remarks from them?

DR WILLIS F. EVANS. The pale, cold, dry skin of patients suffering from myxedema suggested that there might be a decreased amount of blood allotted to the peripheral circulation. The peripheral blood flow has now been measured before treatment and on several occasions during the course of thyroid administration in five subjects exhibiting the signs and symptoms of this disease. In addition, observations of the basal metabolic rate, the circulation time (arm to tongue), the blood pressure, and the pulse rate have been made for correlation with the data relating to peripheral blood flow.

At a time when the basal metabolic rate was low in the myxedematous subjects, the peripheral blood flow was also decreased. With increases in basal metabolic rate toward normal, as the result of therapy, there were successive and

parallel increases in peripheral blood flow. This relationship between metabolic rate and blood flow was linear. The pulse rates and pulse pressures of each of the 5 patients showed trends parallel with changes in basal metabolic and peripheral blood flow, that is to say, they increased with the giving of thyroid. The arm-to-tongue circulation time was measured by means of decholin. Before treatment the circulation time was prolonged. It became shorter during treatment with thyroid.

Measurements of cardiac output have not been carried out in these subjects. However, Stewart, Deitrick, and Crane made such measurements in a group of myxedematous patients and found that it was low at first, and increased to normal with rise in basal metabolic rate upon the administration of thyroid.

Studies similar to the ones just reported have been carried out in 18 patients suffering from hyperthyroidism, a disease at the opposite end of the metabolic scale from myxedema. In thyrotoxicosis, at a time when the basal metabolic rate was high the peripheral blood flow was increased. Parallel decreases in basal metabolic rate and peripheral blood flow occurred during iodine therapy, and both returned to normal levels after subtotal thyroidectomy. If the data relating to blood flow and metabolic rate for the two diseases were plotted on the same chart, a linear relationship would be apparent. With progressive increases from the low basal metabolic level of the myxedematous state to the high basal metabolic level of the hyperthyroid subjects, there was progressive increase in the peripheral blood flow. Recordings of pulse rates, pulse pressures, and circulation times in the thyrotoxic patients were of an opposite order to those observed in the subjects suffering from myxedema.

The cardiac output was measured in one of the hyperthyroid subjects. At first it was markedly increased, and decreased with the administration of iodine and again after subtotal thyroidectomy. Boothby and Rynerson observed that in thyrotoxicosis there was greater increase in cardiac output than occurred in normal subjects as a result of a corresponding increase in oxygen consumption because of work. It was shown that during this time the arteriovenous oxygen was decreased. Stewart, Deitrick, and Crane showed that in myxedema the arteriovenous oxygen difference was increased. Since the total cardiac output and peripheral blood flow were greater than those required for tissue metabolism (as indicated by decreased arteriovenous oxygen difference), the increased peripheral blood flow in thyrotoxicosis served to increase heat loss, whereas the decreased peripheral blood flow in myxedema served to conserve heat.

DR. CATTELL: We would like to round out the discussion with some questions.

DR. CHARLES H. WHEELER: Dr. Cattell, I think it should be emphasized that in cases of myxedema studied by Dr. Harold Stewart some years ago he observed that the heart was enlarged, the circulation time was slowed, the venous pressure was increased, the cardiac output was considerably decreased, and the work of the heart was impaired. With treatment, all of those various functions of the cardiovascular system were restored to normal. In the light of those studies there can be little doubt that myxedema has a definite effect on the heart which perhaps only in a small percentage of cases becomes so marked as to induce symptoms or signs of heart failure.

DR. HENRY B. RICHARDSON: By what treatment were they restored to normal?

DR. WHEELER: By the administration of thyroid substance.

DR. CATTELL: That is in accord with your more recent observations, is it not, Dr. Evans?

DR. EVANS: Yes.

DR. EGGLESTON: I think a very important point to emphasize is that there are changes in cardiac function and that there are changes in the circulation as a whole in myxedema. This is very evident, but that there is any such clinical condition as the myxedema heart, as an entity separate from that due to coronary disease, as we have the hyperthyroid heart which is so frequently seen, appears to be rather doubtful.

These cases in which myxedema is apparently the primary or sole cause of cardiac failure are, I think, indeed rather rare, and it was from that point of view that I was directing my remarks.

DR. RICHARDSON: From the therapeutic standpoint, the circulation in the heart in myxedema is not capable of carrying the load of the normal metabolism if that metabolism is suddenly superinduced artificially by thyroid material.

DR. DuBois: Is not the myxedema patient protected by lethargy?

DR. RICHARDSON: Do you not get the impression that there are many who would have symptoms of coronary disease if they had not been protected from it by the onset of myxedema?

DR. SHORR: Yes.

DR. CATTELL: It is apparent that a sudden increase in metabolism would be harmful, since the necessary circulatory adjustments require a certain length of time, and the heart would not be immediately fit to carry the increased load.

DR. SHORR: There is one point I would like to raise. We are inclined to think that the body is very efficient as a mechanism and that when

things abnormal occur, that very nice adjustments are made to it, but I think that Graves' disease is one example of where the body falls down. As Dr Evans pointed out, the various circulatory indices are far in excess of the metabolic needs, and Dr Conby Robinson a few years ago supplied us with objective reasons for this.

He found in his patients with Graves' disease that the arteriovenous oxygen difference was lower than in the normal. The rapidity with which the blood flowed through the capillaries prevented the organism from taking out as much oxygen per unit of time. Does that not indicate that the speed of the circulation is excessive and out of proportion to the needs in the classic case of Graves' disease? It is possible that this overactivity of the circulation does not occur in the older age group. It may be very well worth while to study it, Dr Evans. In these patients the pulse rate is much slower than one would anticipate from the basal metabolism. There is a basal metabolism of +30 or 40 associated with a pulse of 70. I have often wondered whether or not it might be due to the fact that their vegetative nervous system may be less unstable with less overactivity of the circulation, the arteriovenous oxygen difference would be more nearly normal, and therefore the pulse rate slower. In the young people we find the reverse—the pulse rate rapid, out of proportion to the basal metabolism. Have you any comments on that?

DR EVANS: That has been our observation, the older individuals with the toxic adenoma certainly have slower pulse rates.

DR JANET TRAVELL: I want to turn to another subject. Dr Gold spoke about the use of digitalis in auricular fibrillation if quinidine failed. I wonder whether he would state whether he gives them simultaneously, or whether he stops the quinidine, or whether he allows an interval to elapse between the starting of the digitalis. Another question is digitalis ever dangerous in any of the cardiac manifestations or complications of thyrotoxicosis?

DR GOLD: It is not well to give large doses of quinidine and digitalis together. The two exert a synergistic action which is injurious. The evidence comes from animal experiments and isolated experiences in man. It would take too long to go into the details of the mechanism. When one has given very large doses of quinidine without avail, the thing to do is to discontinue for twenty-four hours, because most of the quinidine is eliminated within that period of time, then digitalize the patient as though he had had no quinidine. On the other hand, if one gives digitalis first, and in fairly full doses, it is better to wait several days before one gives large doses of

quinidine because of the fact that it takes so much longer for the elimination of the digitalis.

As to the toxic effects of digitalis in thyroid disease, up to 1916, I think, in this country it was a pretty general practice to give digitalis to most patients with thyrotoxic disease in an endeavor to control the rapid heart rate. Many of them were poisoned in that way. Out of this arose the belief that digitalis is injurious to the patient already toxic with Graves' disease, a phenomenon similar to the synergistic effect of two poisons. Some have placed the toxic action of the two factors not upon the heart, but upon the brain, resulting in edema of the brain. The evidence is far from satisfactory that ordinary digitalizing doses of digitalis exert a greater toxic effect in the hyperthyroid than in the non-hyperthyroid patient.

DR WHEELER: I would like to ask Dr Shorr whether he believes digitalis is useful in auricular fibrillation due to Graves' disease.

DR SHORR: I think there is no difference between Graves' disease and any other condition in regard to the indications for the use of digitalis. The same factors, auricular fibrillation and failure, are indications for its use, and I believe it has the same effectiveness, with this to be remembered if one gives a patient with Graves' disease digitalis, one should not expect that the heart rate will come down to 70, where one may expect a similar dose to bring it in a person without Graves' disease. The factors which are in control of the pulse are fundamental, they are the requirements of the body. To expect, therefore, that digitalis will do more in case of auricular fibrillation than it will do in a patient with Graves' disease whose pulse rate remains at 100 or 120 without fibrillation is, of course, asking too much.

DR WHEELER: I am interested to hear you say that, because one frequently hears the statement that digitalis is ineffectual in controlling the heart rate in auricular fibrillation in Graves' disease but it has been our observation on the Medical Service in the hospital here that that statement is not true. The rate is not slowed as much as in individuals without Graves' disease, but it is definitely slowed.

DR SHORR: It is like asking digitalis to prevent the expected rise in pulse rate on climbing stairs.

DR GOLD: It is, however, possible, by large doses of digitalis, to block auriculoventricular conduction by a direct extravagal action, and thus reduce the heart rate to fairly low levels. Strictly speaking, this is not a physiologic slowing. It is analogous to heart block by digitalis in a normal person.

DR SHORR: do you mean to convey the idea that

heart failure with auricular fibrillation resulting from Graves' disease responds as well to digitalis as heart failure from other causes?

DR. SHORR: No, in that you have in the non-Graves' individual only a normal load. In the case of Graves' disease you have an unusual load whose diminution is dependent not on the reaction to digitalis but on the reaction to the general therapeutic regime.

QUESTION: In auricular fibrillation do you prefer to withhold quinidine until after surgical intervention?

DR. SHORR: I do not think that quinidine is contraindicated before operation, but I think the possibilities for normal sinus rhythm persisting are distinctly less than after operation.

DR. TRAVELL: Why do thyrotoxic patients go into congestive failure? Is there any evidence that a vitamin B<sub>1</sub> deficiency may act as a precipitating factor in this type of failure? This might be suggested by the known increased metabolic needs for this vitamin and also by the paroxysmal or episodic character of its course.

DR. EGGLESTON: I should like to ask this question: do you think that patients with Graves' disease are as responsive to cardiac failure therapy as the nonhyperthyroid cardiac patient?

DR. CATTELL: Dr. Stewart, would you express your view of that?

DR. HAROLD STEWART: In my experience they recover from heart failure just about as readily as any other patients. It may take them a little longer to become free of congestion.

DR. GOLD: Would you agree to that, Dr. Eggleston?

DR. EGGLESTON: I would say, that before the common use of iodine in detoxifying these patients, it was my impression quite definitely that their likelihood of response to such measures as you have outlined minus the iodine was somewhat less, rather significantly less, than in the patients without hyperthyroidism. Frequently one would not get satisfactory clinical effects, and one would not get satisfactory slowing with digitalis even of the fibrillating heart. I have seen a good many cases where patients have been poisoned by the efforts to slow the heart in the face of thyrotoxicosis that was not recognized, but since the advent of iodine, then I agree with you fully that they respond well. In fact, I question sometimes whether we need the digitalis or the diuretic. Many times if they are simply put at rest in bed and given the usual preparatory treatment of the thyroid with iodine, a high caloric diet, and restricted fluid intake and restricted salt, they will get along with their heart failure and recover without the other methods; not that I advocate that as a procedure, because

I think the other methods added to it hasten restoration.

DR. GOLD: These views concerning the response of the hyperthyroid patient with failure to the usual methods of therapy are extremely interesting. I believe that the more generally accepted view is that patients with hyperthyroidism developing heart failure are likely to be fairly resistant to treatment, and that one of the points which leads one to suspect that hyperthyroidism may be the cause of the failure is that one fails to get very far with the usual methods of treatment. But would you care to say something else about that?

DR. STEWART: Iodine is an essential part of the treatment.

DR. GOLD: As I see it, then, there is no real difference of opinion here; if you treat them with iodine at the same time the response of the failure is very good and much the same as nonhyperthyroid patients. Is that it?

DR. STEWART: I think we might expand a little more on the slowing by digitalis at this point. I think that there is too much emphasis on the point that you cannot slow the fibrillator in hyperthyroidism. You can slow them down fairly well and in many instances even without iodine you can get them down to a fairly low level. It may be somewhat higher than the usual level for other patients. It may take somewhat more drug than the average dose for another patient but it can be done. I have seen no toxic effects from slowing the ventricular rate in these fibrillators.

DR. EGGLESTON: May I speak on that? I believe the reason Dr. Stewart has not seen toxic effects is that Dr. Stewart is skilled in the use of digitalis. We certainly see the toxic effects of digitalis outside an institution such as this. We encounter them in consultation where the physician has not known enough about digitalis to handle it as expertly as you or Dr. Gold can handle it. The average person does not get the slowing in any degree adequate in his estimation to restore a patient unless he uses the iodine, nor does the patient's clinical picture change enough to make him feel satisfied, so he goes ahead and pushes the digitalis a bit too far. I think nausea and vomiting and some of the other toxic symptoms are much commoner outside of teaching institutions than they are here. In other words, what I am trying to say is that you don't induce them because you know better, whereas a good many others, not realizing the situation, do induce digitalis intoxication in their efforts to slow the fibrillating or nonfibrillating heart in the presence of an active thyrotoxicosis.

DR. JOHN B. DEITRICK: May I take up this point? I will differ with Dr. Stewart. Consider

the patient with auricular fibrillation, a ventricular rate of 140, a basal metabolism of +60, and without iodine. I would be greatly surprised if you could lower the ventricular rate more than 10 or 15 beats a minute with digitalis alone, but if you add iodine you can certainly lower it to a great extent in a week or ten days. The iodine, in my experience, is very important. I have never been able to control the ventricular rate with digitalis alone. At the end of a week or ten days with iodine the digitalis works very well. Do you agree with that?

DR STEWART: I think we can show charts where the digitalis alone has caused marked slowing.

DR GOLD: Is it possible that the difference between these two views may be due to the fact that we are talking about different degrees of hyperthyroidism and that patients with extremely high basal metabolisms, who are fairly sick, are likely to be more resistant to digitalis than those with milder grades of hyperthyroidism?

DR DAVID P. BARR: Dr. Gold, may I make a remark about this? It seems to me that to some extent there has been too much emphasis laid on the strict parallelism between basal metabolic rate and pulse rate. In general there is a surprising correlation, and if you take a group of patients you will find that the pulse rate in crease corresponds fairly closely to the basal metabolic rate increase. On the other hand, if you watch an individual patient over a period of time you will find the greatest variation in the pulse rate. I have seen patients who had a basal metabolic rate of +50 and 60 who had a basal pulse of 80 or less, sometimes as low as 75. On the other hand, those same patients in bed on the ward might have pulse rates around 120 to 130.

The idea of controlling all the variations of pulse rate in a patient like that with digitalis is like saying that you are going to control the rate of a man who runs a race with digitalis. It cannot be done. You cannot make the heart rate come down to the desired level by giving digitalis before the race is run. I would agree with Dr. Eggleston that before we used iodine in these patients with decompensation and irregular rhythm digitalis resulted in almost no slowing at all.

DR GOLD: How about those with auricular fibrillation?

DR BARR: It also applies to them, particularly if advanced decompensation is present. Digitalis often fails to reduce their ventricular rate significantly in the presence of thyrotoxicosis.

DR EGGLESTON: I think the situation is analogous to that during active infection. During infection the use of heart rate as a guide to digitalization is futile. There is the toxic in-

fluence which is driving the heart which is more potent than the effect of the digitalis on the rate.

DR GOLD: There is one other point here which perhaps we have partly answered, and that is regarding the sensitivity of the hyperthyroid patient to the toxic actions of digitalis. It is generally stated that the patient with Graves' disease is more sensitive to the toxic effects of digitalis than the non-Graves' patient. Is there anything in that, Dr. Eggleston?

DR EGGLESTON: Not in my experience, Dr. Gold. I think he responds just about the same as the patient without Graves' disease so far as his likelihood of developing toxic symptoms is concerned.

DR GOLD: Yet you did say that, by and large, you encounter more toxicity among patients with Graves' disease treated with digitalis than you do among those who don't have Graves' disease.

DR EGGLESTON: I think it is because of the failure to recognize the fact that thyrotoxicosis antagonizes the effect of digitalis on the rate.

The doctor using rate is a crude guide, pushes digitalis into the toxic range. If he followed those patients by some other means the chances are he could avoid toxicity. Perhaps Dr. Stewart would say whether the effect on the T wave or on conductivity in thyrotoxicosis could be used.

DR GOLD: Is there any difference in the tolerance of the Graves' patient to digitalis by any method of measurement?

DR STEWART: I don't think so. I have not observed any differences, and I don't know of any good experimental work bearing on it.

DR GOLD: There are, nevertheless, the statements in the literature, made by Plummer and others warning against the toxic action of digitalis in Graves' disease, especially a toxic action on the central nervous system causing edema of the brain. Plummer stated that the patients do badly with digitalis even in the presence of an apparently beneficial action on the heart.

DR BARR: What Plummer showed was that during the period in which patients had been routinely digitalized preoperatively, the mortality from thyroidectomy was higher than it had been in the years when they were not so routinely digitalized.

On the other hand, it must be remembered that in this series complete digitalization was attempted and that patients received a full dose, whether they needed it or not. They must have been digitalizing a great number of individuals who would have fallen into the normal range in whom we now believe digitalis may be actually harmful. I never felt that that demonstration of Plummer's was any argument against digitalizing a thyrotoxic patient who was decompensated or

who had some trouble, such as an irregularity of the heart, which might develop into decompensation.

DR. McKEEN CATTELL: I believe that Dr. Gold and Dr. Modell have some observations on patients with fibrillation which bear on the problem of slowing in Graves' disease.

DR. GOLD: There are two ways in which the heart in the patient with fibrillation slows as the result of digitalis. One is a reflex increase in vagal tone from the improvement of myocardial function. The other is an extravagal mechanism in which the slowing is due to the direct action of digitalis on auriculoventricular conduction. In Graves' disease the reflex mechanism may be inactive. Therefore, the digitalis can slow the rate by the remaining mechanism, namely, the direct action on the auriculoventricular conducting system. But this requires a very much larger dose, sometimes twice as much as for the "vagal" slowing. Such large doses under any conditions are likely to give rise to many cases of poisoning.

DR. CATTELL: The patient with Graves' disease is subject to paroxysms of auricular fibrillation. What do we do about that?

DR. EGGLESTON: I used to treat them vigorously. I don't any more, because most of those paroxysms seem to be self-limited and innocuous. If, after subtotal thyroidectomy, the patient continues to fibrillate or if he develops recurrent attacks of fibrillation, I am inclined, provided the patient is still under iodine, to resort to the use of quinidine.

DR. GOLD: Your inclination, then, is not to deal with the paroxysm of fibrillation directly before operation.

How about a case of this kind: A patient is in the ward with auricular fibrillation, being prepared for operation. He is going to be there for two or three weeks and during that time he is having attacks of auricular fibrillation once or twice daily. They last half an hour or an hour. Are you inclined to let him be, or would you do something about the attack?

DR. STEWART: As you describe it, I would do something. If the attacks last long enough, several hours, I think I would digitalize the patient in order to reduce the marked changes in ventricular rate, even though the heart might still go in and out of fibrillation. I do not make any attempt to stop the attacks with quinidine until a certain length of time after operation. Even in these cases I also use digitalis at the same time.

DR. EGGLESTON: How long do you wait?

DR. STEWART: A variable period. I usually wait several weeks. They sometimes return to a normal rhythm spontaneously in two or three months after operation.

DR. EGGLESTON: That brings up a moot point, moot in my mind anyway, as to whether we are running risks of embolism from intra-auricular thrombi in the patient who has been allowed to remain too long in fibrillation or who has reverted to sinus rhythm. I have my own ideas about that.

DR. GOLD: Let us have them.

DR. EGGLESTON: My own ideas are that the transition from fibrillation into a sinus rhythm does not materially enhance the likelihood of embolism.

DR. GOLD: I take it, therefore, that in changing fibrillation to normal rhythm, from the standpoint of danger, you regard it as a matter of indifference whether the fibrillation is one day old or five weeks old?

DR. EGGLESTON: Yes.

DR. GOLD: We have here two different answers to the same question. Dr. Eggleston would use quinidine to control the fibrillation while Dr. Stewart would use digitalis.

DR. EGGLESTON: Just a minute, Dr. Gold. I think that is simply because Dr. Stewart and I are answering the same question from two different points of view. He was talking of fibrillation with heart failure, I think; I was dealing with the problem of fibrillation per se without heart failure. If there were no heart failure present I would not use the digitalis. If there were heart failure I would proceed just as Dr. Stewart and use the digitalis.

DR. STEWART: Whether there was failure or not, I would use digitalis.

DR. GOLD: I think the record is clear on this point. We have two different answers to the same question. That's common enough. So it is also in the literature; some people treat the fibrillation per se, regardless of failure, with digitalis, in the hope of obtaining a slower rate each time the heart goes into fibrillation; others try to control recurrence of attacks with quinidine.

This brings up another point. In a patient who is subject to paroxysms of auricular fibrillation with a very rapid rate, let us say a ventricular rate of 180 a minute, is it your experience that the rate is slower if the patient is kept digitalized?

DR. EGGLESTON: Dr. Stewart was just discussing that question.

DR. GOLD: Dr. Stewart said yes, but I would like to know what you think.

DR. EGGLESTON: Frankly, that has not been my experience.

DR. GOLD: It has not been mine either. We digitalize these patients with average doses, and in spite of it every time an attack of fibrillation pops up, the ventricular rate seems to be as fast as before we gave the digitalis. It is probably largely a matter of dosage.

DR EGGLESTON That has also been my experience

DR GOLD How much quinidine do you give, Dr Eggleston, to prevent attacks of auricular fibrillation in this group of patients?

DR EGGLESTON I usually begin with an initial dose of 0.3 Gm five times per twenty-four hours, as evenly spaced as possible, and work from there up until I find a dose which for that patient suffices to control and produces no toxic symptoms. You, yourself, have mentioned your experiences with very high doses without detriment to the patient. I think the drug has to be given with caution, and only on the basis of trial in the individual patient.

DR GOLD The fact that the patient has hyperthyroidism presents no special problems?

DR EGGLESTON Not in my opinion.

DR GOLD What dose of digitalis do you use to control the fibrillation, Dr Stewart?

DR STEWART If I were going to digitalize I would use 1.8 Gm in twenty-four hours, and maybe a maintenance dose of 0.2 Gm. As I said, in these patients it may take a little more than in other patients.

DR DEITRICK Is there any evidence that the heart suffers permanent damage from hyperthyroidism? Does the presence of auricular fibrillation make it necessary to prolong the period of bed rest and iodine in preparation for operation?

DR GOLD You mean structural damage?

DR DEITRICK Yes.

DR GOLD Is there any?

DR EGGLESTON I wish the pathologists would tell us. The clinical evidence is against permanent damage, because even most of these patients who have been in severe congestive failure during hyperthyroidism return to clinically normal individuals following adequate preparatory treatment and adequate subtotal thyroidectomy. It seems to be a reversible intoxication rather than structural damage. Yet there are statements in the pathologic literature which suggest that there may be some structural damage there. The late Dr Ewing, some years ago, refused to give me a categorical answer to this question. He said that he did not know.

DR STEWART In experimental work with thyrotoxin feeding to animals, they have not been able to demonstrate any morphologic changes. No doubt there must be a functional derangement from which the heart is unable to recover completely, although you are not able to distinguish that heart from another under the microscope.

DR TRAVELL To come back to a point brought up earlier, I believe that Dr Stewart said that he would digitalize a patient and then give him quinidine, isn't that so?

DR STEWART If I were going to give a patient quinidine, I would slow the rate down first by digitalis.

DR TRAVELL I wonder if there are any dangers in the administration of quinidine to a patient who has received large doses of digitalis?

DR STEWART I don't know of any with therapeutic amounts of digitalis.

DR EGGLESTON Wasn't it you who brought out that question?

DR TRAVELL It was Dr Gold.

DR GOLD We found that in animals quinidine and digitalis often acted synergistically to produce toxic effects on the heart. After large doses of digitalis, otherwise safe doses of quinidine sometimes caused cardiac standstill.

DR CATTYL There is also evidence of antagonism between these two drugs.

DR EGGLESTON I think certainly that clinical experience does not serve to point strongly to any inherent danger in the simultaneous use or sequential use of these two agents, quinidine and digitalis.

DR MODELL Since digitalis tends to maintain auricular fibrillation, isn't that a theoretic objection to its use together with quinidine?

DR EGGLESTON I think that is purely theoretic. I don't believe it is borne out by clinical experience. In the patients who have been digitalized the sinus rhythm can be re-established just about as well as in those who never had any digitalis.

DR STEWART There is a group of patients who do not respond to quinidine and in whom digitalis will prevent attacks of fibrillation.

DR EGGLESTON I am very glad you brought that point out, because in theory digitalis should enhance the auricular fibrillation, and there are some patients in whom it does that.

DR GOLD I may direct your attention to the fact that a large proportion of the accidents from quinidine reported in the literature occurred in digitalized patients, and also to the few reports of cardiac arrest from quinidine in digitalized patients. I have seen one such case. It resembled the thing we sometimes see in the dog.

### Summary

DR GOLD We may now briefly summarize the essential points that have been brought out in the conference this morning.

It is perhaps not strictly accurate to regard the cardiovascular disturbances of Graves' disease as complications, but rather as manifestations of the disease, because in the vast majority of cases the heart and the circulation are involved as part and parcel of the complex manifestations of Graves' disease itself. In some of the cases, particularly the older age group, nervous symp-

toms are at a minimum and the cardiovascular signs outstanding. Unless one bears this in mind one is likely to overlook cases of Graves' disease. These are sometimes referred to as "masked hyperthyroidism." The clinical problems are heart failure and the common disorders of rhythm, premature contractions, auricular fibrillation, auricular flutter, and paroxysmal tachycardia. The characteristic of these disorders when due to Graves' disease is the almost complete reversibility in most cases, even in extreme grades. The treatment is essentially the same as when these occur in patients without hyperthyroidism. A significant fact is, however, that the cause can be attacked through at least the partial cure of the Graves' disease itself. This is accomplished by the combination of iodine therapy and subtotal thyroidectomy. Most cases require subtotal thyroidectomy after suitable preparation with iodine administration. The outlook for medical treatment is now improved with the new drug, thiouracil. Cardiovascular disturbances of Graves' disease tend to be more resistant to the customary therapeutic agents. Patients require more digitalis than most patients to slow the ventricular rate in auricular fibrillation, and often the slowing is not as marked. This drug rarely abolishes the auricular fibrillation. Its effect in relieving the congestive heart failure of hyperthyroidism is also usually incomplete. There is no good evidence that patients with Graves' disease are more susceptible to the toxic action of digitalis.

Quinidine is effective in abolishing the auricular fibrillation, but there is difference of opinion as to when it should be used. In view of the fact that prior to operation it is difficult to maintain a normal rhythm even if it is restored by quinidine, some recommend that it be withheld until after thyroidectomy. Others, however, hold the view that a normal rhythm may be restored and maintained with quinidine in most cases if large enough doses are given—10 grains every two

hours until the rhythm is normal (usually 30 to 60 grains in all). The indications are that these large doses are safe, although the view is held by some that they are more likely to cause toxic effects. The sinus tachycardia of Graves' disease does not respond to digitalis or quinidine. Iodine will slow it markedly, but the effects are not likely to be permanent, and in the end these patients are likely to come to operation before a lasting reduction of the pulse rate is achieved. The combined use of quinidine and digitalis, and the dangers of the combination were debated.

The effects of Graves' disease and myxedema on the circulation are opposite; in Graves' disease the pulse is rapid, the cardiac output is inordinately high, the arteriovenous oxygen difference is small, and the peripheral blood flow is high, whereas in myxedema the pulse is slow, the cardiac output is low, the arteriovenous oxygen difference is high, and the peripheral blood flow is low. These are reversed by appropriate treatment: iodine or thiouracil and thyroidectomy in Graves' disease, and thyroid medication in myxedema. The "myxedema heart" as a clinical entity responsible for cardiovascular symptoms is uncommon. The probability is that many of the cases presenting clinical cardiovascular disease in myxedema have concomitant arteriosclerosis. Thyroid materials must be used with caution in myxedema. Small doses, of the order of 30 to 60 mg. daily, usually suffice to relieve the symptoms of myxedema without the danger of putting an excessive load upon the heart through the rapid elevation of the basal metabolic rate. Heart failure as the result of myxedema is rare. Certain disorders of rhythm, however, occur, and these are treated by digitalis, quinidine, or mecholyl, as the need may be, in much the same way as in nonmyxedematous patients. They are sometimes abolished by adequate treatment with thyroid material.

The details of these treatments have been discussed.

#### UNEMPLOYMENT INSURANCE PAYMENTS NOW BASED ON 1943 WAGES

Since June 5, 1944, when the new unemployment insurance "benefit year" began, benefits are paid only on the basis of earnings in the calendar year 1943, Milton O. Loysen, Executive Director of the Division of Placement and Unemployment Insurance, has pointed out.

"Job-seekers who have exhausted their benefits based on earnings in 1942, and who worked in 1943, may file new claims on or after June 5," said Mr. Loysen.

"Persons who have not claimed benefits in the benefit year June 7, 1943, to May 31, 1944, and who worked in covered employment during 1943 have been able to file a claim against their 1943 earn-

ings any time since May 16, 1944. Unemployed workers currently receiving benefits and who remained continuously unemployed until June 4 will experience no lapse in payments if they remained eligible through June 5, provided they are eligible on the basis of their earnings in 1943. They must, of course, report to the local office as directed and file a new claim.

"If a claimant exhausted his benefit rights, based upon his wages in 1942, and the last day he was entitled to benefits was any day up to or including June 3, he must file a claim on or after June 5 and serve a new waiting period in order to obtain benefits," concluded Mr. Loysen.

# Case Report

## MANIFESTATIONS OF HEMOLYTIC PHENOMENA AND INFECTIOUS MONONUCLEOSIS IN A CASE OF LYMPHATIC LEUKEMIA

FREDERIC FELDMAN, M.D., and JACOB J. YARVIS, M.D., Brooklyn

CASES of hemolytic jaundice associated with leukemia have been reported by several authors.<sup>1,2,3</sup> We are reporting a case of this type complicated by evidence of infectious mononucleosis.

### Case Report

The patient, L. B., a boy of 18 years, was admitted to Kings County Hospital on September 18, 1939. He complained of midabdominal pain of five weeks' duration, bleeding from the gums, and passing of dark urine. At the onset he experienced persistent severe ache in the left upper abdomen, occasionally associated with epiploids of colic in the mid-abdomen. He then noticed increasing pallor and he began to complain of marked general weakness.

There was no previous history of jaundice or of his family. His blood count on admission was: hemoglobin 12 gms. per 100 cc., red cells 4,500,000, white cells 20,600, hemoglobin 73 per cent. On October 2 a bone marrow study showed 14 per cent lymphocytes, of which 9 were atypical, polymorphonuclears, 1 per cent, bands, 13 per cent; metamyelocytes, 4 per cent, eosinophils, 1 per cent, promyelocytes, 2 per cent, and normoblasts, 1 per cent. These findings showed some maturation defect of the granulocytes and marked erythroblastosis. There was an increase in lymphocytes, and some of these were atypical and were believed to be the type seen in infectious mononucleosis. Microspherocytosis of the red blood cells was noted in the bone marrow smears.

The gums were heaped and spongy and bled easily to the touch. The mucous membranes of the mouth were pallid. Small discrete glands, about the size of a hazelnut, were felt in the posterior cervical region, the axillae, and the inguinal regions. The lungs were clear. There were systolic murmurs heard at the apex and at the pulmonic area.

On abdominal examination there was tenderness

in the right upper quadrant. The spleen was enlarged and was felt six fingerbreadths below the costal margins. On October 13 the urine was negative for bile although the patient was still jaundiced.

At this time the boy's mother and his sister and brothers were examined. Their spleens were not palpable, they were not icteric, and their blood smears failed to show any evidence of familial icterus.

On October 17 the fragility test was repeated with washed cells. Hemolysis began at 0.54 per cent sodium chloride and was complete at 0.38 per cent.

Intravenous cholecystography revealed a well-filled gallbladder of normal size and function, with no stones.

On November 5 the blood count was: red cells, 2,800,000, white cells, 8,900, and hemoglobin, 50 per cent.

On November 8, blood smear revealed: polymorphonuclears, 25 per cent, bands, 11 per cent;

analysis showed free hydrochloric acid 45 and combined hydrochloric acid 88.

Fragility test showed hemolysis beginning at 0.50 per cent sodium chloride and complete at 0.42 per cent sodium chloride. A heterophile test was positive in 1:1,024 dilution on September 21.

The blood findings suggested the diagnosis of acute infectious mononucleosis and hemolytic icterus. The blood smears were examined by

transfusion of 500 cc. of blood was given without untoward reaction. Subsequent transfusions were difficult because of the presence of auto-agglutination and rouleau formation.

On September 27 the blood count was: red cells 4,500,000, white cells 20,600, hemoglobin 73 per cent. On October 2 a bone marrow study showed 14 per cent lymphocytes, of which 9 were atypical, polymorphonuclears, 1 per cent, bands, 13 per cent; metamyelocytes, 4 per cent, eosinophils, 1 per cent, promyelocytes, 2 per cent, and normoblasts, 1 per cent. These findings showed some maturation defect of the granulocytes and marked erythroblastosis. There was an increase in lymphocytes, and some of these were atypical and were believed to be the type seen in infectious mononucleosis. Microspherocytosis of the red blood cells was noted in the bone marrow smears.

The heterophile reaction was repeated and was again positive in dilution of 1:512. The Davidson

test was specific for infectious mononucleosis.

On October 6 another transfusion was given; this was followed by severe epistaxis. Bleeding time was four and a half minutes. The spleen was now larger and was felt six fingerbreadths below the costal margins. On October 13 the urine was negative for bile although the patient was still jaundiced.

At this time the boy's mother and his sister and brothers were examined. Their spleens were not palpable, they were not icteric, and their blood smears failed to show any evidence of familial icterus.

On October 17 the fragility test was repeated with washed cells. Hemolysis began at 0.54 per cent sodium chloride and was complete at 0.38 per cent.

Intravenous cholecystography revealed a well-filled gallbladder of normal size and function, with no stones.

On November 5 the blood count was: red cells, 2,800,000, white cells, 8,900, and hemoglobin, 50 per cent.

On November 8, blood smear revealed: polymorphonuclears, 25 per cent, bands, 11 per cent;

From the medical services of Dr. Henry Wolfer and Dr. Bernhard A. Fedde, Kings County Hospital, Brooklyn, New York.

lymphocytes, 63 per cent (12 atypical); mononuclears, 1 per cent; and basophils, 1 per cent. The red blood cells again showed microspherocytosis and 4 per cent reticulocytosis.

Because of investigations up to November 15, 1939, it was believed that this case was one of congenital hemolytic icterus aggravated to crisis by an infectious mononucleosis. The patient continued on a downhill course and because of the hemolysis and hemorrhagic episodes, he was transferred to another hospital, where a splenectomy was done. The post-operative course was satisfactory except that healing of the wound was delayed. The hemorrhages and the purpuric manifestations diminished and the hemoglobin and red cell count improved. He was given a transfusion at this hospital and, as before, difficulty was encountered because of the autoagglutination and rouleau formation, and also because of the presence of anti-O agglutinins. An explanation of these reactions and an interpretation of the immunologic features were presented in a separate paper by Wiener *et al.*<sup>4</sup>

An abstract of the pathologic report\* of the spleen follows.

The spleen weighed 2,000 Gm. There was an infarcted area 9.5 by 4 cm. The usual cyto-architecture was difficult to make out because of increased cellularity of the organ. Malpighian bodies were relatively diminished and widely separated. Where present, they showed large germinal centers with but a narrow rim of round cells in them. With a Perles' stain, blue granules of hemosiderin were seen in many of these large cells. There were areas of marked congestion of the splenic pulp in which many of the cells filling the sinusoids were immature red blood cells and white blood cells. These findings were regarded as consistent with a diagnosis of hemolytic icterus.

The patient was sent home, continued under observation, and given two transfusions. He began to have swelling of the abdomen, with increasing purpuric manifestations. His anemia and white blood cells increased and from his symptoms and findings it became increasingly evident that he was suffering from a lymphatic leukemia.

On January 6, 1940, the white cell count was 101,000. By February 12, 1940, his blood count was as follows: hemoglobin, 50 per cent; red blood cells, 2,240,000; white blood cells, 253,000; platelets, 65,000; neutral myelocytes, 2 per cent; polymorphonuclears, nonsegmented, 2 per cent; polymorphonuclears, segmented, 1 per cent; lymphocytes, 93 per cent; lymphoblasts, 2 per cent; normoblasts, 6 per 100 white cells; reticulocytes, 11 per cent.

A bone marrow smear showed marked infiltration with lymphocytes. A heterophile reaction was now positive at 1:128. There still were microspherocytosis and reticulocytosis.

On March 1, 1940, the patient was readmitted to Kings County Hospital, where examination revealed a progressive state of cachexia, severe pallor, icterus of sclera, and moist and clammy skin. There were still the hazelnut-sized glands in the groin, axilla, and cervical regions. The chest revealed moist rales at both bases. The abdomen was increased in size, with a left rectus scar. The liver edge was felt in the right iliac fossa and was tender. Edema extended up from his ankles to his knees.

The blood count was: red blood cells, 2,000,000;

white blood cells, 230,000; hemoglobin, 35 per cent; platelets, 100,000; segmented neutrophils, 12 per cent; nonsegmented neutrophils, 4 per cent; small lymphocytes, 66 per cent; monocytes, 3 per cent; lymphoblasts, 15 per cent.

The heterophile reaction now was negative. Red blood cell count still showed microspherocytosis.

The patient lapsed into coma and expired on March 21, 1940.

## Discussion

This patient was admitted to the hospital with evidence of hemolytic icterus. He was jaundiced and his spleen was enlarged. The blood smears showed microspherocytosis and reticulocytosis. The red blood cell fragility was increased. Autoagglutination, a finding not uncommon in hemolytic icterus, also was present. The urine showed 2 plus bile but this was regarded as due to backing up of bile in the biliary radicles or hepatic cells because of the delivery of excessive amounts of blood pigment to the liver. A month after admission there was no bile in the urine, although the patient was still jaundiced. The blood smears showed atypical lymphocytes which were thought to be the type seen in infectious mononucleosis. Heterophile tests were repeatedly positive, except toward the end of the disease. The Davidson exclusion test, considered specific for infectious mononucleosis, was positive. There were present also purpuric phenomena which at the beginning were thought to be due to the infectious mononucleosis. Because of the downhill course of the patient, increasing anemia, and persistence of hemolysis for months, splenectomy was resorted to. Following this, for a short time, the hemolytic phenomena and blood findings showed slight improvement, only to recur with increasing severity.

Further studies, such as blood marrow smears and blood studies after operation, began to reveal the picture of a lymphatic leukemia.

## Conclusion

A case of lymphatic leukemia is reported in which there was evidence of hemolytic icterus before a diagnosis of lymphatic leukemia could be made. As in the cases of Haden<sup>1</sup> and Brill,<sup>2</sup> splenectomy was performed in the early stages of the disease. In our case, also, there were repeated positive heterophile reactions in high dilution and a Davidson exclusion test was positive. Although the occurrence of these positive tests indicated a diagnosis of infectious mononucleosis, one cannot rule out the possibility that they may have been caused by leukemia. The finding of such reactions by other investigators would, of course, lend credence to this view.

# Medical Indemnity Insurance

*Recent progress of plans for voluntary medical indemnity insurance makes it desirable to publish in the JOURNAL, from time to time, material bearing on this or a related subject. The installment which follows is quoted from an article by C. C. Curtis, M.D., Syracuse, New York.—Editor*

WHETHER we like it or not, medicine is in a transition period. We must face this idea of change. A feeling of unrest is in the air and men's minds are in a ferment. It is proving to be a time of radical change always. With dictatorships tripping men's minds, we must be prepared for repercussions in our manner of living and in the practice of our profession.

If this is true—and I think it is self-evident—what are we going to do about it? Are we going to cooperate and exert some influence in shaping these forces? Or are we to stand aside, do nothing, and have something foisted on us that we do not want?

relationship between the patient and the physician and any scheme that disrupts such a relationship, I believe, strikes at the very base of good medical care. The reason for this is that under our present system of private medical practice the objectives of both the patient and the physician are the same. That objective is to return to good health. The physician wants to return to work and the enjoyment of life, and the patient certainly wants to be satisfied, and pay his bill and get back to work. Both physician and patient lose their interest in getting well and increased morbidity is bound to result.

A second criticism of this type of State medicine has to do with the fact that the recompense is so small per patient that a large number of patients have to be seen in order to provide the practitioner with an adequate income. Quality of service has to be sacrificed to quantity. The answer is obvious. To do his work properly the physician must have time not only to make a diagnosis but to exercise his prerogative as friend, counselor, and guide. He must have time to become acquainted with the total personalities of those under his care, and this has always been impossible under any form of contract practice.

Third, under a system of State medicine another abuse would rapidly develop. The patient would be encouraged to expect more from the State and the State would be expected to pay more for the patient. Caught in this vicious circle, the State would be unable to pay more for the patient and the patient would be unable to expect more from the State.

become more closely knit. He would become merely a bystander.

All physicians would be put on the defensive. They would be caught between the desire of the patient for care and benefits only to be gained by being sick and the desire of the political bureaucratic administration to get results and get the beneficiary back to work. The harassed practitioner, to protect himself, would find it necessary to order all sorts of tests, many unnecessary but all expensive to complete the record and protect himself from being overwhelmed. Every man's hand would be against him and the practice of medicine would cease to be an art, rather degenerating into a series of laboratory tests to find out not what ails the patient but rather to prove whether the patient is a patient or a malingerer.

Fourth, practice would become slovenly. Proper diagnosis would not be made and the patient would either have to be turned over for a mechanized check-up or merely symptomatic treatment. The latter in State schemes is only too often the case. In England under State medicine the people are rapidly becoming drinkers.

A fifth criticism of this type of State medicine is bound to be costly. The cost of such a system is first started, it would be bound to increase as an extensive bureaucratic edifice was built up to administer its workings.

Now, briefly, let us consider the possibility of the second system that I mentioned earlier. It is sometimes erroneously called "social medicine," but, correctly, "sickness indemnity insurance." This form is more than a distinct probability. It is already here. . . . Arrangements are made for the easy payment of premiums. The annual indemnity is limited so that the patient watches his withdrawal from his yearly allowances, thus putting a curb on morbidity that often is encouraged by most State schemes of unlimited service. If the patient has to budget his insurance benefit he is not apt to run to his doctor for every little sickness.

Certainly we can have no objection to this plan, which gives the moderate income group an opportunity to provide itself with medical care on a self-respecting basis. . . . It is the American way, as it tends to maintain the self-respect of the individual because he is doing something for himself. It fosters individualism and a sense of responsibility. . . . We all feel it.

Let us consider the various advantages of a paid physician—at least for the great bulk of the population—and stressing the advantages of sick-

population and tend to combat the various cracked-pot ideas and isms that now seem to plague us.

# Postgraduate Medical Education

*Programs arranged by the Council Committee on Public Health and Education of the Medical Society of the State of New York are published in this section of the JOURNAL. The members of the committee are Oliver W. H. Mitchell, M.D., Chairman (428 Greenwood Place, Syracuse); George Baehr, M.D., and Charles D. Post, M.D.*

## Poliomyelitis Teaching Day in Elmira

A TEACHING Day on poliomyelitis was held at the Mark Twain Hotel in Elmira on July 26, under the auspices of the medical societies of the counties of Allegany, Chemung, Schuyler, Steuben, and Tompkins, the Medical Society of the State of New York, and the New York State Department of Health.

The afternoon meeting was called to order at 3:00 p.m. by Dr. George R. Murphy, regional chairman in pediatrics. Dr. James E. Perkins, Director of the Division of Communicable Diseases of the New York State Department of Health, spoke on "Epidemiology of Poliomyelitis." Dr. A. Clement Silverman, professor of clinical pediatrics at Syracuse University College of Medicine and Director of the Communicable Disease Bureau of the Syra-

cuse City Department of Health, delivered a lecture entitled "Clinical Features—Pathology, Diagnosis, and General Treatment." General discussion followed the lectures.

After dinner at 7:00 p.m. in the Hotel the evening meeting was called to order at 8:30 p.m. by Dr. William R. Phillips. "Physical Therapy in the Acute and Convalescent Stages" was the first lecture, delivered by Dr. William B. Snow, associate in medicine at the College of Physicians and Surgeons of Columbia University. Dr. John C. McCauley, Jr., associate professor of clinical orthopaedic surgery at New York University College of Medicine, then spoke on "Orthopaedic Measures." These lectures were followed by general discussion.

---

## RESEARCH FELLOWSHIPS AWARDED BY NEW YORK ACADEMY OF MEDICINE

Three of four fellowships entrusted to the committee on medical education of the New York Academy of Medicine have been awarded. The fellowships were provided by Charles Mayer of New York City and consist of \$2,000 each. They went to Dr. Harry Goldblatt, associate director of the Institute of Pathology, Western Reserve University School of Medicine, Cleveland, and Philip Handler, Ph.D., associate in physiology and nutrition, Duke University School of Medicine, Durham, North Carolina, for work on "use of choline and other lipotropic factors in the prevention and treatment of fatty infiltration of the liver and hepatic insufficiency." Dr. Richard Lewisohn, of the cancer research laboratory of the Mount Sinai Hospital, New York, was

granted a fellowship for work on "action of ingested choline, lecithin, methionine, and inositol on precancerous lesions and disorders associated with neoplastic diseases." John R. Murlin, Sc.D., professor of physiology, University of Rochester, N.Y., received a fellowship for research on "effects of riboflavin, certain amino acids, and casein on the development and growth of cancer."

The committee on medical education did not receive a satisfactory application for the fourth subject provided for under the fellowships, and no award was made for a study "of the relationship between precancerous lesions of the mouth, hepatic insufficiency, and gastrointestinal disorders."—*J.A.M.A.*, July 8, 1944.

---

## NEW YORK ACADEMY ESTABLISHES BUREAU OF MEDICAL EDUCATION FOR POSTGRADUATE INSTRUCTION

Anticipating an unprecedented demand for postgraduate medical education upon the termination of war, particularly from physicians returning to civil life from service in the armed forces and from civilian physicians from Central and South America, as well as from European countries released from Nazi control, the New York Academy of Medicine has created a Bureau of Medical Education.

The function of this Bureau will be to serve all physicians interested in furthering their medical education, but particularly the physicians returning from the war, and the foreign physicians who come to New York for postgraduate instruction.

The Bureau, organized by and operated under the supervision of the Committee on Medical Education of the New York Academy of Medicine, will render its services without charge.

The Bureau plans to publish announcements of postgraduate medical courses conducted by the universities and the hospitals located in New York City.

Thirty-three of the leading hospitals have been invited to collaborate in this work. A group of advisers representing the special fields of medical practice has been appointed to supervise the work of the Bureau.

## *when apathy prolongs convalescence*

Many convalescent patients, faced with the "drab succession of dreary days", may develop a reactive depression which can markedly retard normal recovery.

This depression may manifest itself in symptoms of apathy, hopelessness or despondency, psychomotor retardation and subjective weakness.

Obviously, the physician should guard against undue stimulation. But when, in his judgment, a convalescent patient will

benefit by a sense of increased energy, mental alertness and capacity for work, the administration of Benzedrine Sulfate Tablets will often accomplish the desired result.

## **BENZEDRINE SULFATE TABLETS** (racemic amphetamine sulfate)

As with any potent therapeutic agent, Benzedrine Sulfate should be administered under the supervision of the physician. Indications and contraindications are set forth in N.N.R.

## Joint Committee Plans Physical Fitness Year

A MAJOR step toward national physical fitness—the planning of a Physical Fitness Year—was initiated under the direction of a Joint Committee of the American Medical Association and the National Council on Physical Fitness, at a meeting at the National Headquarters, Selective Service System, Washington, D.C., on July 14.

The Special Emphasis Year on Physical Fitness is planned to start throughout the country on September 1, 1944.

Col. Leonard G. Rowntree, chief of the Medical Division of National Selective Service, is chairman of the joint committee. Some of the best-known medical men, civilian leaders, educators, and Government executives will help to develop the platform on which the Special Emphasis Year on Physical Fitness will be based and operated. For the first time, according to Colonel Rowntree, organized medicine is joining forces with other professional groups and organizations to develop national plans to meet the problem of the low level of physical fitness existing in the population.

The purpose of the Special Emphasis Year on Physical Fitness is to direct the attention of the public to its responsibilities for a stronger, healthier home front necessary for the successful pursuit of the war and for the peace that will follow victory, Colonel Rowntree said. It is also part of the plan to effect increased activity on the part of all public and private agencies capable of influencing public opinion, providing programs, and operating them wherever possible.

This Physical Fitness Year, according to the Joint Committee, will increase materially the activities and responsibilities of the schools and colleges in matters of physical education, and of Federal, state, and local governments to provide ready opportunities for the improvement of physical health, to coordinate the activities and support of labor and industry, social and religious groups, patriotic groups and professional and amateur sports organizations concerned in this field. The Joint Committee said it would attempt to utilize to the fullest all media of information and promotion and that the platform would include all possible approaches to the problem of increasing physical fitness in the civilian population of America today.

"One of the basic reasons for this Special Emphasis Year on Physical Fitness," said Colonel Rowntree, "is the constant stream of reports continuously coming in to Selective Service from industry and labor, local boards, and induction stations, indicating lack of physical fitness not only among the general population, but especially among the youth of the nation.

"The Special Emphasis Year on Physical Fitness should be approached in much the same spirit as will be the next war loan drive.

"Though much has been done, we face the question, What more can be done? We must make certain that the United States will be better prepared to defend itself in the future. This program must be brought home to every citizen so that their personal responsibility can be assumed for physical fitness. It is the patriotic responsibility of all Americans to be in the best possible physical condition in war and for peace."

The Joint Committee, which met in Washington, is made up of five members appointed by the American Medical Association—Dr. Roscoe L. Sensenich, Dr. Morris Fishbein, Maj. Gen. George F. Lull, Dr. William Stroud, and Dr. L. A. Buie; five members appointed by the Chairman of the National Council on Physical Fitness—Dr. Hiram Jones, Dr. William F. Jacobs, Dr. John F. Studebaker, Mr. Arch Ward, and Mr. A. H. Pritzlaff; Captain C. Raymond Wells, president of the American Dental Association; Mr. Watson B. Miller, assistant administrator of the Federal Security Agency, who will serve particularly to advise on governmental relationships. The president of the A.M.A. and the chairman of the Committee on Physical Fitness are ex officio members; Colonel Leonard G. Rowntree, *chairman*; Frank S. Lloyd, *Secretary*; Dr. Franz Schuck, *Assistant to the Chairman*; and Loretta Flannery, *Recording Secretary*.

The Joint Committee is responsible for the policy, plan, supervision, and evaluation of the Special Emphasis Year. The Committee will meet at the call of the chairman and the expenses of the first meeting will be carried by the Committee on Physical Fitness. This committee prepared the way for the meeting of the National Council on Physical Fitness held late in July.

The Surgeons General of the Army, Navy, and the U.S. Public Health Service will serve in an advisory capacity to the Joint Committee. They are to be kept continuously informed and will provide advice from their own initiative or in the light of the requests from the Joint Committee.

The Advisory Committee on Government Liaison is made up of representatives of the various government agencies which are particularly concerned with this Special Emphasis Year. It included Maj. Gen. Lewis B. Hershey, of Selective Service; Gov. Paul V. McNutt, Federal Security Administrator; Dr. Warren F. Draper, of the U.S. Public Health Service; Mr. Donald M. Nelson, of the War Production Board; Mr. Elmer Davis, of the Office of War Information; Gen. Frank T. Hines, of the Veterans Bureau. Others will be added as necessity may demand.

The Chairman of the Joint Committee appoints individuals to serve as aids to the Joint Committee in areas where coordination is necessary. These include finance, program, manuals, inventory, public relations, and evaluation. It is the responsibility of these coordinators to inform the Joint Committee concerning the effectiveness of the programming in their particular area, paying particular attention to unnecessary overlap and gaps in the general strategy of approach. It is their further responsibility to carry out special tasks assigned to them by the Joint Committee of their particular area of interest. These coordinators have no administrative authority or responsibility in the actual program areas.

The Program Council consists of the chairmen of the various programming sections and other persons appointed by the chairmen. Dr. C. Ward Cramp-ton, of New York City, was elected chairman of the Council.

It is the responsibility of the Program Council to share the plans and experiences of the various sec-

[Continued on page 1700]

**Therapeutic Trojan Horse...** Sulfonamides are bacteriostatic, not bactericidal, not self-sterilizing. Thus a contaminated sulfonamide preparation, applied locally, may act as a therapeutic Trojan horse, releasing pathogenic bacteria inside the body's primary defenses.

Sulfathiadox\* Ointment, however, is *self sterilizing*. This unique preparation contains microcrystalline sulfathiazole, 5%, with oxygen liberating urea peroxide 1%, and chlorobutanol, an antifungal preservative, 0.5%.

'Sulfathiadox' Ointment, recently developed by the Warner Institute for Therapeutic Research, is not only self sterilizing with respect to *Streptococcus hemolyticus*, *Staphylococcus aureus* and *Escherichia coli*, but also for the highly resistant,

spore forming, anaerobic *Clostridium welchii* and *Clostridium tetani*.

The special water washable, oil in water base of 'Sulfathiadox' Ointment assures better 'point of contact' utilization of the sulfathiazole and is readily miscible with purulent and serous exudates. 'Sulfathiadox' Self Sterilizing Sulfathiazole Ointment is supplied in 1 ounce tubes and in 1 pound jars. William R. Warner & Co., Inc., New York 11, N. Y.

**Sulfathiadox**

SELF STERILIZING SULFATHIAZOLE OINTMENT

[Continued from page 1698]

tions, to view the program in its entirety, to recommend these programs to the Joint Committee, and to carry out the instructions of the Joint Committee for more effective planning.

Eight programming sections were appointed: institutional planning, management, labor, promotion, associated industry, schools and colleges, state and local organization, and medical affiliates. New York State workers in the programming sections are Dr. Crampton, chairman for institutional planning; and Dr. Chas. Gordon Heyd, also of New York City, was chosen as cochairman by the A.M.A. Dr. Louis H. Bauer, of Hempstead, chairman for management; Dr. Nathan B. Van Etten, of the Bronx, chairman for medical affiliates; Dr. Kendall Emerson, of the National Tuberculosis

Association; Miss Edith Gates, Director of Health Education of the National Board of the Y.W.C.A.; Samuel D. Gershovitz, camp and health director of the National Jewish Welfare Board; George Hecht, of *Parents' Magazine*; Dr. W. L. Hughes, of Teachers College, Columbia University; Dr. Hiram A. Jones, Director of Physical Fitness of New York State; the Hon. Irving Lehman, of the State of New York Court of Appeals; Msgr. Edward R. Moore, of New York Catholic Welfare; Daniel A. Poling, D.D.; Dr. William A. Sawyer, representing the American Medical Association; and George S. Stevenson, of the National Committee for Mental Hygiene.

The committee has written a seven-plank platform for broad action of a national scale, and steps were taken "to establish general standards for age groups."

### Advisory Council Named to Administer Workmen's Compensation Law

ON JUNE 25, Governor Dewey appointed a state industrial council of nine members, reduced from fifteen, under a reorganization as a result of the recent state investigation into administrative aspects of the Workmen's Compensation Law.

The council's function is that of an advisory body to the state industrial commissioner on all matters relating to the Department of Labor, which, in turn, administers workmen's compensation. Under the reorganization act, which requires three representatives each for employees, employers, and the medical profession, membership of the former council was terminated on June 1. The new unit

includes employee and employer representatives. In addition, medical representatives listed are Albert W. Bailey, osteopath, Schenectady; Dr. Connie M. Guion, New York City, and Dr. Nathan B. Van Etten, Bronx. Dr. Guion and Dr. Van Etten are new appointees, the others having been members of the former council. The reorganization law provides that physicians on the council shall function also as a medical appeals unit which shall "consider all matters connected with the practice of medicine, prescribe rules for the medical practice committee, medical societies, or boards investigating medical violations, and shall review charges for medical treatment and care (of injured workmen)."

### Medical School Enrollment Advanced Three Months

MEDICAL school programs for new civilian students began July 1 instead of October 1, as originally planned. Under recent Selective Service regulations, the only students who could be deferred on occupational grounds were those who had entered a medical school by July 1. The schools, therefore, advanced their matriculation date three months in order to obtain occupational deferments for civilian freshmen for the coming year.

This new plan, which will affect approximately 2,000 students, was developed by the medical col-

leges in cooperation with Army officials and Selective Service authorities. For the next three months students will attend special courses, in some cases doing premedical work under college authorities. The regular medical classes will begin October 1. The program does not apply to the medical schools whose next entering class is scheduled for later than October 1.

At present the Army and Navy together supply about 60 per cent of the medical and dental students, the remainder being chosen from civilian ranks.

### Measles Preventive to Be Available to the Public

IMMUNE serum globulin, one of the discoveries of the war research program and used by the armed forces as a preventive for measles, is being made available to the American people at cost under a plan adopted by the American Red Cross in cooperation with the armed forces and various pharmaceutical manufacturers, the *Journal of the American Medical Association* for July 1 announces. Immune serum globulin is one of the fractions or components of blood plasma. Recently announced studies re-

vealed that it contains all of the antibodies in the blood. So far immune serum globulin has been used only for measles.

Since its discovery, immune serum globulin has been used exclusively by the armed forces. Now that a surplus has been built up beyond the needs of the armed forces this surplus is to be made available at actual cost through health departments to the American people, from whom came the blood plasma providing the new serum.

### Health Board Amends Section on Communicable Diseases

HEALTH Commissioner Ernest L. Stebbins of New York City has announced that the Board of Health at a meeting held July 11 amended Section 89 of the Sanitary Code relating to isolation of persons affected with meningococcus meningitis and poliomyelitis. This action was taken in order to conform with modern public health procedures. While until now isolation in both these diseases was fourteen days, it will from now on be limited until the temperature has reached normal.

In the case of meningococcus meningitis, treatment with sulfa drugs and penicillin has shortened to a marked extent the time of recovery. The organisms disappear very quickly when prompt and adequate chemotherapy has been administered. In the case of poliomyelitis public health authorities have considered that the length of the isolation period may be safely limited to the period when the temperature is above normal.

# EFFECTIVE *Ambulant* THERAPY

Kamadrox fulfills the three demands of the patient in peptic ulcer, gastritis, and gastric hyperacidity: It stops the characteristic pain promptly—keeps the patient ambulatory—permits lesions to proceed to healing. • Kamadrox—composed of magnesium trisilicate (50%), aluminum hydroxide (25%), and colloidal kaolin (25%)—provides promptly effective, profound, and prolonged acid neutralizing power; systematically inert, it cannot lead to alkalosis or acid rebound; it is astringent, demulcent, adsorbent, protective; it exerts no influence on intestinal motility, proves neither laxant nor constipating. Its pleasant taste promptly gains patient cooperation.

## KAMADROX

Kamadrox powder, permitting adjustment in dosage, is supplied in 4-oz. and 1-lb. cans. Kamadrox tablets in bottles of 100 and multiples. Each tablet contains:

Magnesium trisilicate	4 grains
Aluminum hydroxide	2 grains
Colloidal kaolin	2 grains

Dose, 1 or 2 tsp. of the powder, well dispersed in water, t.i.d., p. c. Of the tablets, 2 with water, t.i.d. or q.i.d.

NEW YORK • SAN FRANCISCO • KANSAS CITY

[Continued from page 1700]

The Board of Health also deleted the requirements for the exclusion of contacts to these diseases from school or work.

The amendments as adopted by the New York City Board of Health paralleled the action taken at the recent meeting of the Public Health Council of the New York State Department of Health and are in line with the recommendations of the joint Technical Advisory Committee for the Care of Patients with Anterior Poliomyelitis for the Health Departments of New York City and of New York State.

The members of the Advisory Committee in-

clude: Dr. Edward S. Godfrey, Commissioner of Health, New York State Department of Health; Dr. Ernest L. Stebbins, Commissioner of Health, New York City Department of Health; Dr. Philip Duncan Wilson, chief orthopaedist, Hospital for Special Surgery; Dr. William Benham Snow, Columbia University; Dr. James L. Wilson, Children's Service, Bellevue Hospital; Dr. Tracy J. Putnam, chief, Neurological Institute, Columbia University; Dr. R. Plato Schwartz, University of Rochester; Dr. Kristian G. Hansson, chief of physiotherapy, Hospital for Special Surgery; Dr. Alan De Forest Smith, surgeon-in-chief, New York Orthopaedic Hospital.

## County News

### Bronx County

The offices of the Bronx County Medical Society are now located on the sixth floor of the Rogers Building, 400 East Fordham Road.

### Broome County

Dr. John Sassani recently took up his duties as a medical consultant to the Municipal Welfare Department of Binghamton. He replaced the late Dr. H. B. Marvin.\*

### Cattaraugus County

The county-wide industrial x-ray survey, conducted according to a plan drawn up by the members of the Industrial X-Ray Committee, has been completed. Members of the Committee are: Dr. James F. Durkin, representing the county medical society; Dr. Richard Nauen, the County Department of Health; Mr. Stephen Crowley, labor; Mr. Thomas Sweeney, management; Dr. John Armstrong, the county tuberculosis association, and Mr. James Brnold, the public.

Employees of twenty-five industries representing eight localities were offered the opportunity of receiving a free chest x-ray. The cost of 65 cents per x-ray was borne by the company, with one exception. Three thousand, five hundred and forty-five apparently healthy individuals were actually x-rayed. Confidential reports will be sent out to these persons after the films have been read by the County Health Department. Every employer will receive a statement regarding the general condition of the workers in his plant. It will take about a month for these reports to be prepared and distributed.

The portable x-ray unit was set up in thirteen different places.

Each plant where the unit was set up arranged for secretarial help, necessary dressing rooms, and distribution of identification cards, and made it possible for each employee to have time off for his x-ray regardless of whether or not it interfered with his work.

The newspapers in the county helped materially to make the survey the success it was by printing daily and weekly releases sent to them by the Cattaraugus County Tuberculosis and Public Health Association, which promoted the industrial x-ray survey and conducted a health education campaign, including literature, talks, and movies on the subject of tuberculosis both in industry and in the schools.\*

### Chautauqua County

Dr. Hilding A. Nelson has been appointed chief

of the Emergency Medical Service of Jamestown under the Office of Civilian Protection.

In this role Dr. Nelson will assume responsibility for governmental equipment and medical supplies allocated to Jamestown by the Federal Government. He also will head an organization embracing virtually all the doctors in the city, some ninety nurses, and medical aides, according to Lt. Elmer Lee, executive officer of the Office of Civilian Protection.

Dr. Nelson succeeds Dr. W. Gifford Hayward, who recently resigned. Dr. George W. Cottis set up the Emergency Medical Service but relinquished the post when he became president of the State Medical Society in 1942.\*

### Erie County

Dr. Stockton Kimball, of Buffalo, gave a lecture entitled "Tropical Diseases" at a meeting of the Bradford County (Pennsylvania) Medical Society on June 28.\*

. . .

Dr. A. H. Aaron, of Buffalo, is the new president of the American Gastroenterological Society.

Dr. Aaron, who is professor of clinical medicine in the University of Buffalo Medical School, has been treasurer and vice-president of the association. He is the third Buffalo physician to be president, the others, having been Dr. Allen A. Jones and the late Dr. Charles G. Stockton.\*

### Herkimer County

Two new physicians have located in Little Falls in the offices formerly occupied by Dr. Hans Kotrnetz and his wife, Dr. Margarete Kotrnetz, recently accepted in the medical division of the armed forces, the former as a captain and his wife as a first lieutenant.

The new doctors are Dr. Irwin Freund Forbes and his wife, Dr. Margot Freund Forbes. They studied at the universities of Berlin, Vienna, and Munich, and did postgraduate work in surgery and medicine in European hospitals. From 1935 to 1941 they were in general practice in Berlin, and they arrived in the United States in 1941. At that time they practiced in New Jersey, and prior to coming here the two doctors practiced in New York City. They received their state licenses in 1942.\*

### Nassau County

Dr. Austin B. Johnson, of Cedarhurst, was elected president of the county society at the annual election meeting held on May 22 at Mercy Hospital

in Hempstead. He succeeds Dr. Nathaniel H. Robin, of Hempstead.

Dr. Johnson's former position of president-elect was filled by Dr. William C. Atwell, of Great Neck. Dr. Eugene H. Coon, of Hempstead, was elected vice-president, and Dr. E. Kenneth Horton, of Rockville Centre, secretary-treasurer.

Members of the board of censors are Dr. Milton T. Gaillard, of Baldwin; Dr. R. R. Galione, of Roslyn Heights, Dr. A. Milton Goldman, of Rockville Centre, Dr. James L. Winemiller, of Great Neck, and Dr. Charles Edwin Woods, of Westbury.

Members of the Workmen's Compensation Board named for two-year terms are Dr. Rudolph Dery, of Lynbrook; Dr. Stuart T. Porter, of Floral Park; and Dr. J. Wesley Bulmer, of Glen Cove. Dr. Coon became a delegate to the State Society for a two-year term.\*

#### New York County

Dr. John A. Ferrell has been appointed medical director of the John and Mary R. Markle Foundation for research in medical and physical sciences in the United States and Canada. This appointment was effective as of July 1, 1944.

. . .

At the recent meeting of the American Board of Dermatology and Syphilology held in Chicago, Dr. Howard Fox was elected president for the coming year. Dr. George M. Lewis was named secretary-treasurer.

. . .

The Board of Scientific Directors of the Rockefeller Institute for Medical Research announces the following appointment and promotions on the scientific staff, effective July 1, 1944: new appointment—Dr. René J. Dubos, member; promotions: Dr. Walther F. Goebel, associate member to member; Dr. Robert F. Watson, assistant to associate.

. . .

The following New York City doctors received Certificates of Merit for exhibits at the recent annual session of the American Medical Association in Chicago: Drs. Harry Gold and McKeen Cattell, Cornell University Medical College, for the exhibit on "Recent Developments in Digitalis"; Drs. Kurt Lange and Linn J. Boyd, New York Medical College, on the Use of Fluorescein to Determine the Adequacy of Circulation."

Dr. Alfred E. Cohn, since 1920 a member of the Rockefeller Institute for Medical Research, has been made member emeritus of the institute, having reached the retirement age. Dr. Cohn graduated at Columbia University College of Physicians and Surgeons in 1904, joined the Rockefeller Institute in 1911, and became an associate member in 1914; he has been a member of the China Medical Board of the Rockefeller Foundation since 1934.

. . .

Dr. David W. Park resigned his position as superintendent of Potsdam Hospital, Potsdam, effective July 1, to become field representative of the American College of Surgeons. For the time being he will continue to live in Potsdam.

. . .

Dr. Henry Greenwood Bugbee was awarded the Keyes Memorial Medal at the fifty-sixth annual meeting of the American Association of Genito-Urinary Surgeons in Stockbridge, Massachusetts, held June 8, 9, and 10. The award was presented to Dr. Bugbee because of his outstanding scientific contributions to urology and his constructive influence as an officer and counselor of various urologic societies. The Keyes Medal has previously been bestowed to only three outstanding medical or research workers.

#### Oneida County

Two speakers were heard at the Academy of Medicine meeting in the Utica on June 22.

Dr. Eugene N. Boudreau, of Syracuse, read a paper on "The Social and Medical Challenge of Alcoholism," and Maj. George Burgin, Little Falls, recently returned from the Pacific area and cited for rescuing a fellow officer while under fire, related some of his experiences.

Dr. Boudreau cited some of the treatments that have proved effective in chronic alcoholism. He said the cause of delirium tremens and psychosis evident in such cases has not yet been determined. He made a statistical report of the vulnerable cases which will need attention during the next three years and said between 40,000 and 50,000 chronic cases will exist in the nation by 1947.

Dr. Ross D. Helmer opened the discussion on Dr. Boudreau's paper.\*

#### Rensselaer County

The Troy Veterans Information Service Center, a central clearing house for all activity dealing with rehabilitation of returning veterans, now is completely ready for functioning.

Through the center, forty-eight agencies in Troy, all equipped in some way to assist veterans as soon as they make known their difficulties, are united.

Services available will touch on the following activities: canteen, children's service, civil service, education, employment, financial aid, health, general information, insurance, job training, legal aid, mental hygiene, recreation, re-employment, rooms, veterans services, welfare.

The type of service provided by each of the forty-eight agencies has been arranged in a cross-indexed directory. The directory was compiled by James C. Turner, John J. Dougherty, and Samuel W. McCochrane.

By means of the directory, a veteran applying at any agency may, in a few minutes, find the exact station to assist in his case, thereby saving duplication of effort and loss of time.

Discussion at a committee meeting on June 23 centered on the handling of cases involving mental or nervous ailment and requiring the service of a psychiatrist to help decide on readjustment treatment.

Joining in the discussion were Dr. A. W. Pense, assistant commissioner in the State Department of Mental Hygiene, Dr. Richard P. Doody, president of the Rensselaer County Medical Society, and Dr. James C. Boland, Troy health commissioner.

Several actual case studies now available were presented for the occasion. The study of the subject will be continued until a solution is determined.\*

#### Schenectady County

Dr. Walter W. Goddard, who was the first intern to serve a full term at Ellis Hospital, is retiring

# SOPRONOL *Inhibits* FUNGOUS INFECTIONS

MONILIA  
albicans

EPIDERMOPHYTON  
inguinale

MICROSPORUM  
audouinii

TRICHOPHYTON  
purpureum

... As demonstrated by clinical investigation  
in a leading United States hospital

In tests on a large number of hospital patients, Sopronol was found to exert an *inhibitory* rather than a destructive action on the fungus. The advantages of this method are obvious. Sopronol, taken readily into the fungous organism, prevents its development and spread. Hence the infection is quickly brought to an end, but without the customary skin irritation caused by poisonous by-products resulting from strong fungicides in contact with the mold. The chemical basis of Sopronol is sodium propionate.

## ALL SUPERFICIAL MYCOSES (RINGWORM)

Prescribe Sopronol for: Tinea Pedis, Tinea Cruris, Tinea Capitis, Tinea Glabrosa, due to "the dermatophytes"—Trichophyton, Epidermophyton, Microsporum, Monilia (Candida) and pathogenic aspergillae infections. Sopronol is non-irritating, non-keratolytic, non-toxic.

Available in alcoholic solution, powder  
and water soluble ointment bases

MYCOLOID LABORATORIES, INC., Little Falls, New Jersey

from local practice after fifty years of medical service in Schenectady.

He has been a member of the board of directors of the Eastern New York Orthopedic Hospital Association (Sunnyview) since 1929 and has also served as its treasurer.\*

#### Seneca County

A Baumanometer was presented by the county society at a recent meeting in Waterloo, to Dr. Fredrick W. Lester, Seneca Falls physician and surgeon, in recognition of fifty years of service in Seneca County.

The presentation was made to Dr. Lester by Dr. Walter M. Pamphilon, a member of the medical staff of Willard State Hospital.

Dr. Lester, who is secretary of the county society, began his practice of medicine in Seneca Falls on July 15, 1894. Except for the period during World War I, when he was in the Army Medical Corps, he has maintained his practice in Seneca Falls.

A native of Seneca Falls, Dr. Lester was graduated from Seneca Falls Academy in 1888 and studied medicine in the College of Physicians and Surgeons at Columbia University. His father, the late Dr. Elias Lester, also a physician, practiced medicine in Seneca Falls for many years.

For two years, Dr. Lester served in the Army Medical Corps in World War I. He went overseas as a captain early in the war and was in command of Base Hospital 51 on March 31, 1919, when he was ordered back to this country. He now is lieutenant-colonel in the U.S.A. Medical Corps Reserve.

Dr. Lester also is a member of the Seneca County Tuberculosis and Public Health Committee, Kirk-Casey Post, American Legion; Lt. Cyrus Garnsey, 3rd, Post, Veterans of Foreign Wars; Henry T. Noyes Camp, Sons of Union Veterans; Military Order of the Loyal Legion; the Seneca Falls Historical Society, and the Medical Society of the State of New York.\*

#### Warren County

A detailed review of uses and therapeutic re-

sults of penicillin was given on June 16 by Lt. Comdr. R. C. Arnold of the U.S. Public Health Service at a dinner meeting of the county society in the Glens Falls Country Club.

Lt. Comdr. Arnold illustrated his discourse with a series of slides and charts. He has been doing research with the drug at the Marine Hospital, Clifton.\*

#### Westchester County

In an effort to control and treat rheumatic heart disease in Yonkers, the Yonkers Tuberculosis and Health Association on June 22 adopted a pioneering program for the establishment of a special clinic for "the prevention, control, and study" of the malady, and for a coordinated, city-wide educational project.

It was declared to be the first comprehensive, over all, and inclusive project of its kind in the country in this field.

The clinic will be located at St. John's Riverside Hospital and will be completely equipped and financed by that institution. It is expected that patients with rheumatic heart disease now being cared for at Yonkers General and St. Joseph's Hospitals will be referred to St. John's.

The Tuberculosis and Health Association will provide a special worker, trained in nursing, social work, and medical studies. Her assignment will be to study and work with patients at the clinic; to study the home background of rheumatic children and their siblings, and to serve in an advisory and teaching capacity for nurses of the City Health Department, the Visiting Nursing Association, and hospital and school nurses.

Dr. Herbert W. Schmitz is the cardiologist in charge of clinic work for rheumatic heart disease cases in two Yonkers hospitals and also attending physician at Irvington House in Irvington. Mrs. Marie F. Kirwan is executive secretary of the association.

Dr. William J. Vogeler, association president, appointed a committee on administration of the clinic, to include: Dr. Edwin C. Coyne, Dr. Michael F. Sullivan, Dr. Virginus Minervini, Dr. Schmitz, Dr. Vogeler, and Mrs. Eleanor Benedict, with Mrs. Kirwan as committee secretary.\*

# Health News

## Miss Sheahan Becomes President of N.O.P.H.N.

Marion W. Sheahan, R.N., director of the New York State Health Department's Division of Public Health Nursing, was elected president of the National Organization for Public Health Nursing for the biennium 1944-46 at the recent meeting of the organization in Buffalo. She previously held the office of first vice-president.

Miss Sheahan has been a member of the N.O.P.-H.N. for a number of years and has participated actively in its work. For several years she was chairman of the Records Committee and during 1943-44 she was chairman of the Postwar Planning Committee. She also held the chairmanship of the Committee on Nursing Administration, by virtue of which she was the nursing representative on the Committee on Administrative Practice of the American Public Health Association.

## Health Unit Thirty Years Old

The Bureau of Health Education of the New York City Health Department marked its thirtieth anniversary on July 1, it was announced by Health Commissioner Ernest L. Stebbins.

"Since 1914," he said, "the bureau has steadily expanded its facilities, until today it makes use of every recognized publicity medium to teach good health to the people. Booklets and posters, lectures and movie showings, news releases and special exhibits—these are just a few of the tools used by the bureau in its continuous war against disease."

During its thirtieth year alone, according to Savel Zimand, its director, the bureau supplied the public between 200,000 and 300,000 booklets and pamphlets on health topics each month, arranged about 250 motion pictures showings and many lectures and exhibits, and prepared weekly programs on health for local radio stations.

## Scope of Health Service is Broadened

On July 3 President Roosevelt approved legislation broadening the scope of the United States Public Health Service and in a statement commended the department for "its excellent record in protecting the health of the nation."

The act authorizes Federal grants for research by nongovernment institutions, larger appropriations to aid state public health work, and the establishment of a national tuberculosis program. It also provides commissions for public health nurses.

## Community Service Society Reports on Year's Activity

More than half of the families aided by the Community Service Society of New York City last year received nursing and health services, according to the annual health services report of the agency.

Nursing and health services were provided for 33,155 persons in more than 16,500 New York City families during the year, representing 59.2 per cent of the total number of families assisted. For the two preceding years the proportion was 58.9 per cent and 60 per cent.

In addition to the number of persons served in the nursing and health plan, more than 50,000 school children were aided by a continuing dental-nutrition program conducted by the society in fifty-two public and parochial schools in Manhattan.

The agency's nutrition bureau aided members of 1,180 families during the year, with an estimated attendance of 3,000 at individual diet conferences, group talks, and nutrition classes.

The society's medical clinic at 29 Park Avenue provided care for 2,436 patients in 11,000 visits during the year. Its four dental clinics treated 12,242 patients, who made more than 80,000 visits, according to the report.

## Information Available Regarding Health and Welfare of Children

The attention of all practicing physicians in New York City is called to the accessibility of information with regard to facilities for the health and welfare of children.

The Information Bureau of the Children's Welfare Federation at 435 Ninth Avenue (just above 34th Street) has been functioning for some years as a direct service to professional workers and others who need current information. This Bureau keeps in touch with every type of child health and welfare work carried on in New York City, such as child health services, maternity services, and camping facilities. In 1943, eight thousand, one hundred and sixty-five inquiries were answered.

A call in person or on the telephone (Medallion 3-3105) is invited whenever a doctor would like up-to-date information on facilities that are available for dealing with any problem of child health or welfare.

## Nutrition Information for Public Health Nurses

In response to many requests from public health nurses, the State Department of Health is distributing monthly, through its staff nutritionists, a new four-page leaflet, *Nutrition Highlights*.

As its name implies, this publication gives in compact form information on nutrition which may be readily utilized by the public health nurse in her daily work. The leaflet includes a "Question Box," up-to-the-minute news under the heading, "What's New," and references to scientific literature as well as to popular pamphlets on nutrition under the caption "Interesting Reading." Future issues will carry résumés of nutrition experiences of public health nurses in the field. It is hoped that all members of nursing groups will send in contributions and suggestions.

*Nutrition Highlights* has a circulation of approximately 2,500, restricted to public health nurses. The Department will furnish this publication, to the extent of its facilities, to nurses doing public health work within New York State who may be interested in receiving it. Requests should be addressed to the New York State Department of Health, Bureau of Nutrition, Bond Building, 76 State Street, Albany 7, New York.

## Physical Education in High Schools

Only half of the boys and less than half of the girls in the last two years of high school are now receiving organized instruction in physical education, according to data just made available by the U.S. Office of Education, the Federal Security Agency has announced. This means that about 1,100,000 juniors and seniors in high school are not receiving instruction in physical fitness, F.S.A. said.

According to an estimate for the whole country, based on reports from nine hundred and ninety-two school systems of all sizes, 50.1 per cent of the boys in the eleventh and twelfth grades are now enrolled in physical education classes. Only 46.7 per cent of the girls in the same grades are enrolled in such classes. These figures reveal a 6.3 per cent increase over 1942-1943 in the number of boys receiving physical education and a 4.5 per cent increase in the number of girls, despite the fact that total enrollments of boys and girls in those grade decreased 15.2 and 5.2 per cent, respectively, at the same time, F.S.A. said.

"Though there has been an increase in physical education enrollment, more widespread development of physical fitness must take place if physical requirements of men for the armed forces are to be met, and young women are to be able to take up their wartime responsibilities," Dr. Bess Goodykoontz, Assistant U.S. Commissioner of Education, said. "According to indications, nearly all boys and many girls now juniors and seniors in high school will be in the armed forces or essential industry before the war is over."

Instruction in health education is being given to a smaller percentage of junior and senior boys and girls than is physical education. About 20 per cent of these students are enrolled in these classes this year. This figure represents a 2 per cent increase in this kind of instruction over 1942-1943.

Among reasons preventing greater increases in enrollment in physical fitness classes is the fact that many men teachers of physical education have gone into the armed forces, F.S.A. said. Schools that wished to inaugurate physical fitness programs have often been unable to find trained personnel. In addition, many small high schools have not had funds with which to hire trained teachers of physical education or to purchase needed equipment. Since small high schools enroll about one-third of the high-school pupils in the United States, neglect of physical training in this category of schools is a serious problem, F.S.A. said.

## Service Women's Health at High Level

Health among uniformed women of the armed forces is at a high level, and the average Wac, Wave, Woman Marine, or Spar improves physically after her enlistment, the Office of War Information has reported, on the basis of data from the armed forces.

Waves have increased their weight by an average of five pounds and were found to be without nutritional deficiencies in clinical tests, according to U.S. Navy findings in a test group of 6,400. In another test group, comprising 2,000 Waves, posture and foot defects showed improvement after a period of training. Decided improvement in posture and carriage, considered important to physical health, was accomplished through training. Women Marines show a gain of five to six pounds in weight after entry into the Women's Reserve.

Health safeguards for Wacs, Waves, Spars, and Women Marines include preventive measures established through inoculations, physical training, and proper food, good housing and living conditions, and proper recreation, according to Army and Navy officials. Those who require it receive ample, prompt medical or hospital care.—Release from the Office of War Information.

## Other Americas Provide Funds for Extended Health Work

Six of the other American republics have concluded new agreements with the United States for extension of the inter-American health and sanitation program. They are Brazil, Mexico, Colombia, Peru, the Dominican Republic, and El Salvador.

The agreements are the first to be made for extension of the program which grew out of the Rio de Janeiro Conference of American Foreign Ministers. Nineteen American republics, including the United States, are cooperating in this program.

The new agreements call for a total of \$16,250,000 in joint funds to carry on health and sanitation projects in the six republics to the south. Of this sum more than half is to be contributed by the other American republics and the balance by the United States, through the Institute of Inter-American Affairs, an agency of the Office of the Coordinator of Inter-American Affairs.

The Brazilian agreement sets up a joint fund of \$8,000,000 over the next five years largely for continuance of health and sanitation projects in the Amazon and Rio Doce valleys in support of economic developments under way there. Brazil is underwriting \$5,000,000 of this fund and the United States the rest. The Brazilian agreement was the first for extension of the program.

The arrangement with Mexico calls for equal contributions toward a \$5,000,000 fund for health work to be carried on for the next five years. The cooperative work in Mexico, as projected, includes provision of additional health facilities along the route of the Inter-American Highway, and participation in campaigns for prevention and control of tuberculosis and other diseases along the 1,800-mile United States-Mexican border.

The Peruvian extension is for three years and provides for a joint fund of \$1,000,000 made up of equal contributions of \$500,000. The new funds will enable Peru to extend work on health and sanitation facilities in the Amazon basin and at Chimbote.

El Salvador has agreed to contribute \$300,000 for continuance of the inter-American health work within her boundaries during the next three years. This sum is being matched by the United States. As the program has developed in El Salvador, contributions by the federal government of El Salvador have been supplemented in many instances by contributions from municipalities. Key towns and cities have been provided with sewerage and water supply systems and drainage ditches for elimination of malaria swamps.

The pact with Colombia provides for equal contributions of \$600,000 to carry on for a two-year period projects for the training of nurses and other public health personnel, for operation and construction of health centers and dispensaries, and for malaria control. Much of the work in Colombia is located in regions producing rubber, balsa, quinine, and other strategic materials.

## NO SYNTHETICS ADDED...

*Apolarthron is the only high potency preparation of vitamins A and D derived entirely from natural sources. No synthetic vitamins are added or used in its manufacture.*

Hence, Apolarthron contains none of the toxic products, such as tachysterol and toxisterol, which are formed when vitamin D is prepared synthetically from ergosterol.

The proven greater safety of the

combined use of natural vitamins A and D makes Apolarthron an outstanding contribution to the treatment of arthritis—a chronic disease which requires intensive treatment with massive dosage of vitamin D over an adequate period of time.

Each capsule of Apolarthron contains 25,000 U.S.P. units of natural vitamin D and 30,000 U.S.P. units of natural vitamin A.

# APOLARTHRON

[Continued from page 1710]

The agreement with the Dominican Republic is for a three-year period. Under its terms a joint fund of \$450,000 is to be set up. These funds are expected to enable the island republic to expand and accelerate work for malaria control.

All cooperative work under the new agreements will continue to be carried out by the special cooperative health services organized in each country.

These services are headed by a United States doctor or sanitary engineer and staffed largely by public health technicians from among nationals of the other Americas.—*Release from the Office of the Coordinator of Inter-American Affairs.*

### West's First Public Health School Opens

The first School of Public Health west of the Mississippi has been established on the Berkeley campus of the University of California, it is announced by President Robert G. Sproul.

With Dr. Walter H. Brown, chairman of the department of hygiene, as acting dean, the school was set up by the Board of Regents after the State Assembly passed a bill appropriating funds. It is an answer to the intensified wartime demand for well-trained personnel to fill the depleted staffs of county health offices in California and other western states, which fear a shortage of facilities for meeting serious public health dangers.

Planned as a University-wide undertaking using

resources of all campuses, the school is being organized as a cooperative enterprise, involving the participation of several other schools and departments, including the fields of medicine, medical research, education, nursing, home economics, and sanitary engineering. The department of hygiene will be renamed the department of public health and will function as part of the school.

Provision for courses and curricula on both undergraduate and graduate levels is contemplated, and plans will be developed regarding graduate training of health officers, epidemiologists, public health engineers, industrial hygienists, and other specialists.

The first official activity of the school will be a special training course for sanitarians to meet the needs of the State Department of Health in the war emergency.—*Journal of School Health, June, 1944*

### New Officers of Health Officers Association

The New York State Health Officers' Association which met in Saratoga Springs June 27-28, elected the following officers for the coming year: president, John R. MacElroy, M.D., Jonesville; first vice-president, George E. Sanders, M.D., Greece; second vice-president, Burdge P. MacLean, M.D., Huntington; third vice-president, Robert Broad, Ithaca; secretary, Russell H. Wilcox, M.D., Tonawanda; and treasurer, H. Burton Doust, M.D., Syracuse.

### AWARD FOR RESEARCH IN HUMAN FERTILITY

The Planned Parenthood Federation of America officially announces an award of \$500 to be presented in 1944 to the scientist who has made the most significant contribution to research in human fertility—either in the control of conception or in the correction of sterility. Eligibility is not limited to any one country, and any scientist anywhere in the world may compete. The purpose of the award is to stimulate increased research in the medical aspects of human fertility.

The closing date for the submission of entries will be December 31, 1944. The judges of each submitted work will be the members of the Medical

Committee of the Planned Parenthood Federation which includes Drs. Richard N. Pierson, Robert L. Dickinson, Nicholson J. Eastman, S. Bernard Wortis, Harvey B. Matthews, H. McLeod Riggins, Abraham Stone, Sophia J. Kleegman, and George D. Cannon. . . .

The initial award is the gift of Mrs. Albert D. Lasker and will be known as the "Mary Woodward Lasker Prize." In addition to this cash prize, a number of plaques will later be presented to other investigators who have made important contributions in this field of science.—*Human Fertility, March, 1944*

### WAC NEEDS ADDITIONAL TRAINED MEDICAL TECHNICIANS

The Women's Army Corps needs additional trained medical technicians. Physically qualified young women with high-school education are urged to make application for enlistment in the Wac service with the medical department. Maj. Gen. Norman T. Kirk, Surgeon General of the Army, re-

cently sent out an appeal for women volunteers in hospital work. The Army offers training to competent young women enlisted in the Women's Army Corps in the field of medical laboratory, dental, x-ray, and other technical subjects.—*J.A.M.A., July 8*

### O'CONNOR IS RED CROSS CHAIRMAN

President Roosevelt has appointed Basil O'Connor, head of the National Foundation for Infantile Paralysis, as chairman of the central com-

mittee of the American Red Cross to succeed the late Norman H. Davis.

Mr. O'Connor will serve without salary.

## *Vitamins Alone* **MAY NOT BE ADEQUATE**

The current popularization of the importance of vitamins, though true in most respects, may prove harmful because of the decreased emphasis placed upon other essential nutrients. A good nutritional state can be achieved and maintained only by satisfying *all* nutritional requirements, not merely vitamins, but minerals and proteins as well.

A food supplement in the literal sense of the word, Ovaltine is a balanced mixture of nutrients which provides virtu-

ally all metabolic essentials. When taken three times daily with the average diet, it makes good the deficiencies usually encountered, and converts the total daily intake to nutritionally satisfying levels. Thus a state of optimum nutrition can be attained, one in which *not only* vitamin requirements are met, but also mineral, protein, and caloric requirements are satisfied. This delicious food drink appeals to patients of all ages, young and old, and is usually taken with relish.

## WMC Launches Campaign to Recruit Nurses

THE War Manpower Commission, through its Procurement and Assignment Service, in cooperation with the American Red Cross, has launched a campaign to recruit at least 8,500 nurses for the U.S. Army and U.S. Navy, WMC Chairman Paul V. McNutt announced on July 18.

The nurses, the WMC chairman said, will be recruited at the rate of 1,000 a month for the Army and 500 a month for the Navy, until a total of 5,500 have been recruited for the Army and 3,000 for the Navy.

Mr. McNutt said most of the nurses needed by the Army and Navy will be drawn from lists of nurses maintained by State committees under which nurses are "classified" on a voluntary basis as "available" for military service "after giving consideration to essential civilian services." A portion of the required number of nurses will be recruited from the U.S. Cadet Nurse Training Corps sponsored by the United States Public Health Service.

The nurses to be recruited for the Army are within the quota of nurses announced in May of this year, Mr. McNutt said. In planning the invasion of France, the Army found it necessary to speed up the recruitment, he said.

Mr. McNutt pointed out that it is possible to recruit the required number of nurses for the armed services without handicap to civilian services, since there are approximately 170,000 nurses in active civilian service and 112,300 student nurses in training.

"If we are going to meet the needs of the Army

and Navy it will be necessary for us to use the skills of nurses as effectively as possible," said Mr. McNutt. "The success of our nursing program depends in a large part on the cooperation of the nursing profession. In addition, we must have the cooperation of physicians, hospitals, and patients to prevent waste of professional skills. It is important that we use these skills to the best advantage. We must see to it that our fighting men have the nursing attention every American family wants them to have.

"It is particularly important that nurses who are available for service with the armed forces volunteer for such service."

The WMC chairman said approximately 50,000 nurses are now serving with the Army and Navy. Almost 8,000 of these nurses were obtained through WMC's Procurement and Assignment Service in cooperation with the American Red Cross since January 1, 1944.

The nurses will be recruited at a time when they will have the advantage of being appointed with actual army rank instead of the relative rank which they have held prior to this time. An executive order signed by President Roosevelt on July 12 gives nurses in the Army the full authority of their officer rank. Previously, nurses could not claim dependency allowance and upon retirement received only benefits attached to their permanent rank rather than being permitted to retire in grade. In addition, their commissions were granted by the Surgeon General with the approval of the Secretary of War instead of by the President.

## Institute for Hospital Administrators to Be Held September 11-22

CONDUCTED for the first time in its twelve-year history by the American College of Hospital Administrators, the Chicago Institute for Hospital Administrators will be held at International House at the University of Chicago, September 11-22. Formerly sponsored by the American Hospital Association, the institute will be under the direction of Dr. Malcolm T. MacEachern, Chicago, who has been its director since its inception.

The institute will provide, for the first time, an intensive series of lectures on a particular phase of hospital administration. Each day throughout the course an authoritative expert will lecture on administrative methods of financial control in hospital operation. In addition to this specialized part of the institute, each morning program will include lectures by hospital leaders on such topics as the hospital in the community public health program,

organization, basic principles, professional and non-professional services, standardization problems, administrative control of services to patients, the patient's environment, medical staff and the specialized departments, nursing service and nursing education, and numerous other aspects of hospital management.

There will be lectures in the forenoons, seminars and field trips in the afternoons to selected Chicago hospitals for demonstrations, and evenings will be devoted to conferences on administrative and departmental problems facing hospitals.

Registration will be limited to one hundred hospital administrators and assistant administrators. Applications for registration may be made through Dean Conley, executive secretary of the American College of Hospital Administrators, 18 East Division, Chicago.

## Port Chester Hospital to Teach Nursing

THE United Hospital in Port Chester has established an affiliation program with the Adelphi College School of Nursing, Garden City, which will return the Port Chester institution to the field of nurse training on a scientifically advanced basis. The program will become effective on September 18, when the first group of student nurses will arrive at the hospital.

The United Hospital operated its own Nurses' Training School, which attracted girls from many

parts of this country and Canada, until 1937. Some months ago, however, hospital officials began to consider re-establishing a nurses' training program, because the severe shortage of graduate nurses and because of the amount of greatly needed clinical material available for trainees at this hospital.

The Adelphi College School of Nursing was incorporated January 28, 1943. It is the first central collegiate school of nursing under a state-wide

[Continued from page 1716]

program to coordinate facilities of liberal arts colleges and the hospitals and health agencies of the community. Moreover, it is one of the largest collegiate schools of its kind in the United States. Of three hundred and thirty-five students enrolled, three hundred and three are in the Cadet Nurses Corps. An additional two hundred and fifty student nurses will be admitted during the next academic year.

Girls in the School of Nursing receive their clinical training in cooperating hospitals and health agencies, which include: Nassau Hospital at Mineola, Queens Hospital at Jamaica, Meadowbrook Hospital at Hempstead, Nassau County Hospital at Farmingdale, Mercy Hospital at Rockville Centre, the Central Islip State Hospital at Central Islip, the Nassau County Department of Health, and the United Hospital, Port Chester.

The original class at United will number about thirty-five student nurses. This group will have had one year of college work at Adelphi and will affiliate at United Hospital for twelve months. Two classes will be accepted yearly, in June and September. There will be approximately sixty-five students in attendance at the hospital at all times after the program gets under way. The agreement creating this affiliation was signed by James E. Stiles, chairman of the board of trustees of Adelphi College, and William A. Pond Phipps, president of the board of trustees of the United Hospital.

The negotiations and the operation of the program will be under the direction of Paul Dawson

Eddy, president of Adelphi College, and Carl P. Wright, Jr., superintendent of United Hospital, together with Miss Mildred Montag, director of the School of Nursing, and Miss Harriet Klein, director of nursing at the hospital.

The School of Nursing offers two programs of study. The first provides for two years of academic work and two years of clinical experience. At the end of the four-year course, a bachelor of science degree and a diploma in nursing will be awarded.

The second program is designed for the war emergency and consists of nine months' academic program followed by twenty-one months of clinical experience.

At the end of this period, thirty months, a diploma in nursing will be granted and the student will be eligible to take the New York examinations for license as a registered professional nurse. She may, at the end of the war, return to college for one year of academic work, and upon completion of that year, be granted the bachelor of science degree.

The U.S. Cadet Nurse Corps, which has a unit at Adelphi College, provides an unequalled opportunity for girls to study nursing. Any student admitted to the Adelphi College School of Nursing who is 17½ years of age is eligible for membership in the Corps. In return for a promise to remain in active nursing (either civilian or military) for the duration of the war, members of the Cadet Corps at Adelphi receive tuition, fees, books, uniforms, and maintenance. In addition, they receive a monthly stipend of \$15 for the first nine months and \$20 for the next twenty-one months.

### Survey Shows Extent of Postwar Building Expectations

**P**ROPOSED nonfederal hospital building that will require an expenditure of \$1,193,133,985 and will provide 180,626 new hospital beds may be anticipated on the basis of reports from 1,683 hospitals tabulated in a survey being conducted by John N. Hatfield, chairman of the committee on governmental aid for postwar construction of the council on governmental relations of the American Hospital Association. Mr. Hatfield, administrator of the Pennsylvania Hospital, Philadelphia, headed the committee investigating postwar hospital conditions in this country.

"In arriving at this conclusion," Mr. Hatfield said, "it is assumed that the nonreporting hospitals require expansion in the same ratio per existing beds as those cooperating in the survey."

Hospitals numbering 897, or 53.3 per cent of those reporting, indicated some building plans, the com-

mittee reported. These institutions house 246,243 beds, or 70.5 per cent of the facilities in the reporting hospitals. Reports were received from a broad cross section of the hospital field, including a ten-bed hospital planning to spend \$30,000 and a one thousand five hundred-bed hospital planning to spend \$2,000,000 for plant expansion.

Ninety-five of the reporting hospitals already have projects under way, seventy have definite plans for 1944, and five hundred and eighty-two are leaving their plans for the postwar period.

A total of seventy-four hospitals reporting have cash on hand for financing of their postwar plans; three hundred and thirty will need government funds; and the others will raise money from private financing, public campaigns or subscriptions, hospital income, and miscellaneous or undetermined sources.

### Improvements

Alterations are in progress at the Nursing Education Center of the St. Lawrence State Hospital in Ogdensburg to provide additional classrooms, a laboratory, and a study room. Dr. John A. Pritchard, superintendent, has announced.\*

\* \* \*

Peekskill's first tangible gift from contributions given to the National Foundation for Infantile Paralysis is a mobile respirator, purchased by the Westchester Chapter of the Foundation at a cost of more than \$2,500 and officially presented to the Peekskill Hospital on June 22.\*

\* \* \*

At a recent meeting of the Executive Board of the Eastern Long Island Hospital a letter was read from Mrs. Alice Stokes, widow of the late Dr. John Stokes of Southold, donating the x-ray laboratory equipment owned by Dr. Stokes to the Eastern Long Island Hospital.

It was voted that in the future the x-ray laboratory at the hospital be known as the Dr. John Stokes Memorial Laboratory.\*

\* \* \*

The Women's Hospital Club of Malone has voted to furnish the Alice Hyde Hospital with an infant incubator.\*

## Reduced Fatalities in Chinese Wounded

Lieut.-Gen. Robert Kho-sheng Lin, chief of the

that has been made in medical care of soldiers in his country since 1937.

China's most serious medical problem, during its war years has been the critical shortage of trained medical personnel for the army. This has required an emergency training of young medical aides. In Free China today, there are only some 6,000 fully-trained M.D.'s, of which one-half are serving in the army.

To partially offset this deficiency, eight thousand

they go into the field to help carry the burden of treating wounded soldiers. Six emergency medical service training schools were organized partly with the help of funds supplied by the American Bureau for Medical Aid to China, and maintained by funds obtained from the United China Relief through the National War Fund.

Proof of the worth of the emergency medical service training schools is shown in the fact that fatalities among Chinese wounded, which was as high as 50 per cent in 1937 and 1938, are now only about five per cent.

### Seesaw-ed Back to Life

the inventor, Dr. Frank C. Eve, an English physician. The victim is strapped to a seesaw (the child variety)

the Eve idea requires no skill or special training as

that the diaphragm, which controls inhalation and expiration, quickly loses its ability to function in drowning persons. The back and forth motion re-

Dr. Eve, even though

without strain on the operators.

The idea dates called to treat a choking to death. ting off her breath. Covering a rocking chair with blankets, the physician tied the tiny sufferer to it and tilted her back and forth until the lungs had driven the obstruction out of her throat.

# Effective Convenient Economical

THE effectiveness of Mercurochrome has been demonstrated by more than twenty years of extensive clinical use. For professional convenience Mercurochrome is supplied in four forms—Aqueous Solution in Applicator Bottles for the treatment of minor wounds, Surgical Solution for preoperative skin disinfection, Tablets and Powder from which solutions of any desired concentration may readily be prepared.

## Mercurochrome

(H. W. & D. brand of merbromin,  
dibromoxymercurifluorescein-iodium)

is economical because stock solutions may be dispensed quickly and at low cost. Stock solutions keep indefinitely.

Mercurochrome is antiseptic and relatively non-irritating and non-toxic in wounds.

Complete literature will be furnished on request.

**HYNSON, WESTCOTT  
& DUNNING, INC.**  
BALTIMORE, MARYLAND

[Continued from page 1716]

A new system has been put into effect at the Tarrytown Hospital which will enable the general public to obtain a doctor for emergency calls at all times, regardless of the hour, day, or night.

Miss Madge Grace Cook, superintendent of the hospital, has explained that a large bulletin board has been set up at the hospital listing the doctors' names alphabetically with phone numbers beside the names, and followed by a blank space in the right hand column. If an individual has exhausted

all efforts to obtain a doctor he can call the hospital. The hospital will then contact the first doctor on the list. If he takes the emergency call, his name card will be slid into the right-hand column and he will not again be called upon until the entire list is exhausted.

In addition to the bulletin board record, Miss Cook will keep a notebook, noting down the number of times a doctor has been called upon in an emergency situation and also the number of times he has been able to go out on these calls.\*

### At the Helm

Roland M. Dearing, of Denver, Colorado, has been appointed superintendent of Potsdam Hospital to succeed Dr. David Park, who resigned to accept a post as field representative of the American College of Surgeons, Clarence E. Premo, president of the board of directors of the hospital, has announced.

Mr. Dearing is a native of Indiana. From 1936 to 1940 he was administrative assistant, admission officer, and credit manager of the Children's Hospital, Denver.

He succeeds Dr. E. A. Lopez, who resigned from the post last spring.\*

. . .

Mrs. Charles Tod Newberry, of Irvington and Charles D. Millard, of Tarrytown have been elected to the Board of Directors of the Tarrytown Hospital.\*

. . .

Dr. Edwin D. Daily, who has been in charge of the Children's Bureau Emergency Maternity and Infant Care Program for servicemen's wives and babies, is leaving that post to serve with the Army in re-establishing civilian medical and hospital services in liberated countries.

At the annual meeting of the members of Northern Westchester Hospital Association directors elected for the 1948 class were William Ewing, Colonel T. P. Luquer, William J. O'Brien, and Lester C. Remsen.

Following the annual meeting of the members, the board of directors met and re-elected the following officers for the ensuing year: Carl Tucker, president; Ralph T. Walker, executive vice-president; Thatcher T. P. Luquer and Edwin G. Merrill, vice-presidents; Theodore C. Slosson, treasurer; and William J. O'Brien, secretary.\*

. . .

The election of Perry Hall as a director of Beekman Hospital in New York City has been announced.

Mr. Hall is a trustee of The Seeing Eye, Inc., a trustee and member of the finance committee of the United Hospital Fund, and a member of the War Finance Committee of New York State.\*

. . .

Dr. Robert Emmet Walsh, of New York City, consulting surgeon at St. Joseph's Hospital in Yonkers for several years, has been appointed chief of surgery at St. Joseph's, Mother Mary Josephine, Mother Superior of the Sisters of Charity of St. Vincent De Paul of Mount St. Vincent, has announced.

Dr. Paul P. Welsh, of Le Roy, has been elected vice-president of St. Jerome Hospital's staff, and Dr. G. Henry Knoll, of Le Roy, chief of the medical service.

Other officers named are: President, Dr. Robert A. Wohlfeil, of Elba; chief-of-staff, Dr. William D. Johnson, of Batavia; director of obstetric service, Dr. L. F. Quinlan, of Batavia; secretary and treasurer and director of urologic service, Dr. D. G. Ribby, of South Byron; director of pathologic service, Coroner Irwin A. Cole; head of nose and throat service, Dr. Carl C. Koester, of Batavia; head of ophthalmologic service, Dr. E. G. Wilson; director of dermatologic service, Dr. F. R. Hall.

. . .

### Newsy Notes

Dr. Charles F. Kivlin, for forty-five years a member of the surgical and medical staff of the Troy Hospital, was tendered a testimonial dinner by members of the hospital staff on June 22 at the Troy Country Club in recognition of his forty-fifth anniversary as a practitioner.

Dr. Kivlin, a native of Troy, was graduated from Albany Medical School in 1898 and spent the next year as intern at the Troy Hospital. Thereafter, he became a member of the medical and surgical staffs and served several terms as president of the staff.

During World War I he served overseas, with rank of major, in the Army Medical Corps.

The informal program at the dinner was conducted by Dr. Hugh V. Foley. The principal talk was given by Dr. Eugene McGillian, Yonkers, a native of Green Island who interned at the Troy Hospital and, while there, was assistant to Dr. Kivlin.

Dr. John T. H. Hogan, an associate of the honor guest, and Dr. John O. Sibbald, at present president of the staff, paid tribute to the honoree. The

## IODINE...

### Its Lasting Effectiveness

Iodine solutions, applied to the skin, continue their bactericidal action for several hours. This is important in surgery where it is desirable that a bactericidal barrier be maintained on the skin to minimize danger of pathogenic organisms from the air.

A further advantage of Iodine is the fact that it does not destroy normal leucocytic function.

Iodine's antiseptic value is in no way affected by the presence of alcohol.

## IODINE

latter presented the guest with a gift on behalf of the staff.

Mason General Hospital, at Brentwood, was formally turned over to the United States Army on June 21 at dedication ceremonies on the grounds of the institution. Maj. Gen. Eugene Reybold, Chief of Engineers of the Army, made the presentation of the buildings, which were accepted by Col. Cleve C. Odom, commanding officer at the hospital. State Senator Perry B. Duryea gave the dedicatory address. Maj. Gen. Norman T. Kirk, Surgeon General of the U.S. Army, praised the maintenance of the hospital and the work of the staff, whose aim primarily is to return as many patients as possible to some form of duty. Only in his address, Maj. Gen. Thomas A. Terry, Commanding General, Second Service Command, traced the history of the hospital and expressed the Army's gratitude to the State of New York for their cooperation in permitting the establishment of the hospital in Brentwood.

Lt. Col. Henry F. Ford and Lt. Hugo Mantel, post chaplains, delivered the invocation and benediction, respectively. A portrait of Brig. Gen. Charles Field Mason, for whom the hospital is named, was unveiled by the General's granddaughter, Miss Mary Page Mason, of Virginia. Approximately four hundred persons, mainly officials and residents of surrounding communities, were guests at the ceremonies, which were also attended by the entire civilian and military personnel at the hospital.\*

A definite five-year program in nursing has been established jointly by the University of Buffalo and the Buffalo General Hospital. The program, leading to both the diploma in nursing and the degree of bachelor of science in nursing, will provide an integrated curriculum so that a student will be able to complete in five years both a university education, which normally requires four years, and nursing training, which normally takes three years.

Students are being enrolled now and the program will start in September. Applications are being taken at the General Hospital.

The five-year program will be offered in addition to the hospital's three-year basic program which leads to the diploma in nursing.\*

Doctors and nurses of Base Hospital 23 soon will be able to view in action members of their families living in this city and elsewhere. A reel of color film of parents, wives, children, and other relatives of members of the hospital staff has been completed and is on its way overseas, it was announced by Dr. Fraser D. Mooney, superintendent of Buffalo General Hospital, which organized and staffed the institution.

Col. John G. Knauer, of the Army, is superin-

tendent of the Base Hospital, but all the other fifty-five doctors and nearly all the one hundred nurses formerly were associated with Buffalo General Hospital. Among them are the head of the medical department of Base Hospital 23, Lt. Col. Werner J. Rose, and Lt. Col. Baxter Brown, surgery-head.

Among the interesting features of the film are views of babies, whom their fathers will see for the first time, and children now walking, who were in perambulators when the Unit left the country.

Base Hospital 23 was organized by Buffalo General Hospital in the summer of 1941, moved to Camp Mead, Maryland, on July 15, 1942, and went overseas in August, 1943.

The film opens with this inscription: "To the doctors and nurses, with sincere regards from Buffalo General Hospital."\*

The women's division of the War Finance Committee of Patchogue, with Mrs. Fannie Goldstein as chairman and Mrs. May Kane as cochairman, took as its particular objective in the Fifth War Loan Campaign the purchasing of hospital equipment. The buying of "mercy equipment" especially appealed to the women's organizations. Mrs. Frances S. Johnson was appointed women's campaign chairman.

The drive was started by the Hadassah, the Daughters of Israel Jacob, and the Sisterhood of the Jewish Center, who, working together, pledged to raise \$75,000.

Last year the women concentrated on hospital equipment and raised over \$128,000.

Twenty-two organizations were represented, including Patchogue Sorosis, Daughters of Israel Jacob, Daughters of the American Revolution, Senior Ladies Aid Society of the Lutheran Church, Episcopal Guild, Baptist Church Ladies, Sons and Daughters of Liberty, Elks Auxiliary, Women's Society of the Congregational Church, Companions of the Forest, Hadassah, American Legion Auxiliary, Catholic Daughters of America, Seton Hall Auxiliary, Order of the Eastern Star, Order of the Amaranth, Junior League, Methodist Women's Society for Christian Service, International Sunshine Society, Pulaski Social Club, Dorothea Rebekah Lodge, and Sisterhood of the Jewish Center.\*

New Rochelle Hospital's board of governors, meeting at the hospital, received a check for \$13,000 from the League for Service and another check for \$4,419.76 from a three-community church bridge committee.

Mrs. H. W. Herrick, retiring president, presented the League's check, which represented receipts from a Spring Fashion Show and Movie, the Hospitality Corner at the Hospital, and the Thrift Shop. The sum brings the total amount contributed to the Hospital by the League for the fiscal year, ending June, 1944, to \$18,000.\*

## NEW GRANTS INTENSIFY THE FIGHT AGAINST POLIOMYELITIS

Outstanding universities, laboratories, and organizations from coast to coast have received twenty-seven grants, totaling \$1,128,770, through the National Foundation for Infantile Paralysis. The fields of virus research and physical medicine will be especially strengthened.

Two five-year grants provide for the establishment of "Units for Research and Physiology as Related to Physical Medicine" at the Medical School of the University of Minnesota and at Northwestern University Medical School. Studies will be pursued relative to the use of electricity, light, heat, cold, rest, exercise, and other physical measures in diagnosis and treatment, and the effects of these forces on nerves and muscles damaged by infantile paralysis.

The Unit at Northwestern University will be under the direction of Dr. A. C. Ivy, chairman of the department of physiology, and Dr. Maurice B. Vischer, head of the department of physiology at the University of Minnesota, will direct the program there.

A third five-year grant went to the University of Michigan School of Public Health, to expand its virus study unit, under the direction of Dr. Thomas Francis, Jr., professor of epidemiology. This unit provides for virus research and training of virologists, and studies will be undertaken to discover how the disease becomes established in a community and how it spreads. Special emphasis will be placed on developing inexpensive and practical methods of rapidly identifying the poliomyelitis virus.

A list of the grants and the institutions which received them follows.

*After-Effects.*—University of Minnesota, Minneapolis, \$320,000; Northwestern University Medical School, Chicago, \$175,000; University of Rochester School of Medicine and Dentistry, Rochester, New York, \$18,000; The Children's Hospital, Boston (two grants), \$11,900; University of California Medical School, San Francisco, \$6,500; Massachusetts General Hospital, Boston, \$3,600; Marquette University School of Medicine, Milwaukee, \$1,500. Total—\$536,500.

*Virus Research.*—University of Michigan School of Public Health, Ann Arbor, \$325,000; Michigan Department of Health, Lansing, \$23,360; University of Wisconsin, Madison, \$10,400; New York University College of Medicine, New York City, \$9,180; Wayne University College of Medicine, Detroit, \$9,010; Stanford University, California, \$8,000; University of Pennsylvania, Philadelphia, \$5,000; University of Minnesota, Minneapolis, \$2,450. Total—\$392,400.

## "We" Borrow Money to Pay Doctor First

According to the deduction of the editor of *Ameri-  
can Weekly*, we Americans are more worried about  
how and where we're going to be buried than with  
keeping alive and healthy.

At least, in personal loans, about 22 out of every  
100 of us have to borrow to meet doctor, dentist and  
hospital bills. But less than one in a hundred causes  
financial trouble when he dies. That's how we  
nts of one of our largest

financial advances made  
by that company last year, 22.5 per cent went to  
pay medical bills. Less than one per cent for funeral  
expenses.

More than 14 per cent of all individual borrowings

help out their families—far ahead of the 53,000 who  
wanted mo  
47,000 for  
for clothing

We get out of hook in about 18 months. Our  
average need was \$156 in 1943 and \$107 in 1941  
In the past 15 years less than one-half per cent of  
American borrowers were "dead beats."

We may not be thrifty—but we're honest.

**TABLETS FOR** *Oral USE—*  
**AMPULS FOR** *Injection*

There has long been a real need for a potent, mercurial diuretic compound which would be effective by mouth. Such a preparation serves not only as an adjunct to parenteral therapy but is very useful when injections can not be given.

After the oral administration of Salyrgan-Theophylline tablets a satisfactory diuretic response is obtained in a high percentage of cases. However, the results after intravenous or intramuscular injection of Salyrgan-Theophylline solution are more consistent.

Salyrgan-Theophylline is supplied in two forms:

**TABLETS** (enteric coated) in bottles of 25, 100 and 500.  
 Each tablet contains 0.08 Gm. Salyrgan and 0.04 Gm. theophylline.

**SOLUTION** in ampuls of 1 cc., boxes of 5, 25 and 100;  
 ampuls of 2 cc., boxes of 10, 25 and 100.

*The macrocytic anemias  
in pregnancy respond to*

# Solution LIVER EXTRACT *Lederle*

**M**ACROCYTIC ANEMIAS in pregnancy resemble other macrocytic anemias. This type of anemia frequently responds best to a complete antipernicious anemia regime, including the injection of liver extract, vitamin therapy, a diet adequate in protein, and iron by mouth when there is evidence of hypochromia.

REFINED SOLUTION LIVER EXTRACT *Lederle* is a potent preparation of the antianemia substance which, because of exceptional care and expense in preparation, causes a minimum of discomfort at the time of injection. Use of this liver extract may be expected to result in a prompt reticulocytosis, a progressive reversal of the abnormal erythrocyte picture, and simultaneous correction of symptoms.

#### PACKAGES

##### REFINED SOLUTION LIVER EXTRACT

# War *in white*

Always exposed to enemy fire, bombing, the field clearing-station surgeons work under the worst hazards ever faced by "soldiers in white." Naturally, their brief respites . . . the occasional "breaks" for smokes . . . are delightful moments.

More delightful because their cigarette is likely to be a Camel... the milder, more flavorful brand favored in the armed forces.\*

Today... as in the first world war... Camel is the "soldier's cigarette," every puff a cheering highlight in a fighting man's life.

## *1st in the Service*

\*With men in the Army, the Navy, the Marine Corps, and Coast Guard, the favorite cigarette is Camel. (Based on actual sales records.)

## *When a woman* **WANTS** *a baby*

Human sperm, in contact with hostile genital secretions, apparently suffer early immobilization—particularly if the seminal picture is characterized by a low sperm count and feeble motility.\*

In clinical tests, a pre-coital douche of Nutri-Sal (a physiologic glucose douche powder) has been found to promote fertility in many stubborn cases free from detectable deficiencies or pathogenies. In temporarily relieving local incompatibility, it also supplies the nutrient glucose, metabolized by the sperm for motile energy.

The results obtained with Nutri-Sal may obviate the necessity for more elaborate diagnostic procedures. Ortho Products, Inc., Linden, N. J.

# THESODATE *Brewer*

(the original enteric-coated tablet of Theobromine Sodium Acetate)

*for*

CLINICALLY EFFECTIVE

LOW TOXICITY

EFFECTIVELY ENTERIC COATED

## CORONARY ARTERY DISEASE AND EDEMA

/ Medical authorities in journals and books have substantiated the value of Theobromine Sodium Acetate in treating certain Cardiovascular and Renal Diseases. Actual clinical use has proven the usefulness of Thesodate (Brewer).

The enteric coating of Thesodate tablets permits adequate dosage, so necessary for best results with xanthines, for as prolonged a period of time as necessary.

Supplied with or without Phenobarbital, also with Potassium Iodide and Phenobarbital, in potencies for controllable dosage.

*Samples and literature on request.*

TO PLACE MORE PENICILLIN  
IN THE HANDS OF THOSE WHO NEED IT

## PENICILLIN *Schenley*

WHEN the great need for Penicillin developed, it was natural that, with experience in the field of mycology and fermentation research, Schenley should turn its extensive facilities to this humanitarian cause

The full-time services of our research staff were immediately applied to the task of perfecting a large-scale *Penicillin*-producing method. Progress was sufficiently successful to earn a place for Schenley among the 21 firms designated for production of the precious drug.

Today, *Penicillin* Schenley is augmenting the nation's supply of this valuable antibacterial agent. Our goal in these efforts is to aid in furnishing sufficient *Penicillin* to fill the fullest needs of both military and civilian medicine.

## THERAPEUTIC TEAMWORK

### Vitamin "B" Complex fortified with Vitamin "C"

Research has shown that vitamins B and C appear to work as a team in effecting beneficial changes in cellular physiology. This was clinically manifested by improvement in pathology of the upper respiratory mucosa and the retina when the two vitamins were given together. When only one was used, this favorable reaction did not occur.

Vitamin "B" Soluble (Walker) is derived from brewers yeast—its potency increased so that three capsules meet the minimum daily needs for vitamin B factors recommended by the U. S. Government.

Professional samples sent on request to Myron L. Walker Co. Inc., Mount Vernon, New York.

**VITAMIN "B" SOLUBLE  
(WALKER)**

# ANATOMY OF PREGNANCY

*This series of life-size sculptured models  
was executed for S. H. Camp & Company  
by Charlotte S. Holt*

**4 Lunar Months**—Abdominal protrusion beginning. Uterus becomes abdominal organ. Fundus 4 cm below umbilicus. Approximate time of quickening. Normal visceral relationship. No appreciable change in body mechanics.

**7 Lunar Months**—Beginning tension on recti. Uterine fundus 5.5 cm. above umbilicus. Cephalic presentation determined. Visceral displacement (upward and lateral). Lumbar and dorsal curves increased. Relaxation of sacro-iliac and pubic joints.

**10 Lunar Months**—Overdistension of recti and diastasis are obvious. Fetus and placenta fully developed. Head engaging (LOP.). Marked visceral displacement (upward and lateral). Marked lumbar lordosis "pride of pregnancy." Relaxation of pelvic joints.

## "YOU'LL FIND THE SPA A FRIEND IN TIME OF NEED, AS I HAVE"

*... says the harassed practitioner  
whose wartime load it has helped  
to lighten.*

Saratoga Spa is accommodating an unusually large number of patients suffering from such conditions as cardiac, vascular or rheumatic disorders which may be aggravated by wartime strain.

A large proportion of these men and women are patients of practicing physicians who have found the treatments here very

beneficial to former patients.

The facilities which New York State has erected around the famed mineral waters of the Spa are extensive. They will provide amply for the needs of your own patients for whom restorative treatment is indicated, under regimens of care which you yourself have recommended.

For professional publications of The Spa, and physician's sample carton of the bottled waters, with their analyses, please write  
W. S. McClellan, M.D., Medical Director, Saratoga Spa,  
155 Saratoga Springs, N. Y.

# SARATOGA SPA

THE EMPIRE STATE'S CONTRIBUTION TO THE MEDICAL PROFESSION

"SINCE the days when a mitral lesion consigned a patient to chronic invalidism", tremendous progress has been made in the treatment of cardiac disorders—so that a much more optimistic prognosis now prevails toward cases of coronary disease<sup>1</sup>

The keynote of today's therapy is "special care over the periods of the acute and subacute phases"—or symptomatic relief with the avoidance of undesirable side reactions

This is capably accomplished in many cases with Calpurate—a unique chemical combination of calcium theobromine and calcium gluconate. While it (1) effectively eases venous congestion through a potent vasodilating and diuretic action, and (2) increases cardiac output through myocardial stimulation—Calpurate is remarkably free from gastric irritation, being almost insoluble in the stomach, yet readily absorbable in the intestine<sup>2</sup>

REFERENCES—(1) Boyer, N. H. J. A. M. 122 307, 1913 (2) Clement, S. C. Med Rec & Ann 38 755 1914 (3) Gilbert, N. C. Quart Bull North Western Univ Med School 16 179, 1942 (4) Gilbert, N. C. & Kerr, J. ### Case A. C.

SYMPTOMS: Sore throat—pain on swallowing

Temperature 100-102°

BACTERIOLOGICAL FINDINGS: Throat culture

showed hemolytic streptococci

DIAGNOSIS: Acute ulcerative stomatitis

TREATMENT: One White's Sulfathiazole

Gum Tablet chewed for 1/2 hour every

2 hours for 6 doses

RESULTS: Immediate improvement—

lesions healed and temperature normal

after 72 hours

This actual case report typifies the response to this new, effective method of providing local chemotherapy in oropharyngeal infections. Further indications include acute tonsillitis and pharyngitis, septic sore throat, infectious gingivitis and stomatitis caused by sulfonamide-susceptible microorganisms. Also suggested in the prevention of local infection secondary to oral and pharyngeal surgery.

Important: White's Sulfathiazole Gum provides a high, sustained salivary concentration of locally active sulfathiazole (70 mg. per cent)—with negligible systemic absorption. Even with maximal dosage, blood levels seldom approach a level of 0.5-1 mg. per cent. Thus untoward systemic reactions are clearly obviated.

## White's

# SULFATHIAZOLE GUM

Available in packages of 24 tablets, sanitized in slip-sleeve prescription boxes—on prescription only.

# Bread plays a triple role

ENERGY

PROTEIN

PROTECTIVE

**I**N today's nutrition picture, physicians will find bread fills three important needs.

It is an energy food, a protein food, a protective food.

Bread has long been recognized as an abundant and convenient source of food-energy. It is plentiful, inexpensive and a favorite food with everyone.

As a source of protein, recent studies\* show that on the basis of average per capita consumption, bread supplies an important percentage of a person's protein intake.

And today bread is also a protective food. Specifications call for all white bread to be enriched. So it now supplies not only carbohydrates and protein but also vitamin and mineral factors — thiamin, riboflavin, niacin and iron.

So all-in-all, in these days of unusual effort, and food shortages, bread stands out as a sound fundamental part of every normal diet — a valuable weapon in the armamentarium of the physician called upon to prescribe foods basic to good nutrition.

\*Block and Bolling, J. Am. Diet. Assoc. 20:69, 1944.

## Bread is basic

Most Good Bread Is Made With

## FLEISCHMANN'S YEAST

# Accent on *Velvet Smoothness*

The process used in manufacturing the "RAMSES"\* Flexible Cushioned Diaphragm produces a dome which is soft and pliable and can best be described as being as smooth as velvet.

This velvet-smoothness lessens the possibility of irritation during use.

The "RAMSES" Flexible Cushioned Diaphragm is manufactured in sizes of 50 to 95 millimeters in gradations of 5 millimeters. It is available on the order or prescription of the physician through any recognized pharmacy.

# To Speed The Day

The promise of penicillin . . . precious, life-saving antibiotic derived from *Penicillium notatum* . . . will not be fully realized until this drug is available in sufficient quantities to work its miracles in every city, town, and hamlet in the country.

Cheplin Biological Laboratories are actively engaged in the production of penicillin and are making intensive efforts to increase its output to the point where all restrictions on its civilian use can be removed. We are doing our utmost to speed the day when this drug will be found in every physician's bag and every pharmacist's prescription room.

# How DRYCO meets infant feeding needs...

**New Improved DRYCO** is a scientifically adjusted milk food, designed only for infant nutrition. Because of its high-

protein, low-fat content, it can be used alone, with carbohydrate, with milk, or with milk and carbohydrate.

**What DRYCO is made of**—DRYCO is made of superior quality whole milk and skim milk, with no non-milk substances except pro-vitamin A and vitamin D.

For optimal nutrition, DRYCO supplies ample potencies of vitamins A, B<sub>1</sub>, B<sub>2</sub>, and D, and important milk minerals.

**How to use DRYCO**—New Improved DRYCO is quickly soluble in cold or warm water.

Prescribe one leveled tablespoonful per pound of body weight daily, plus sufficient carbohydrate to meet caloric needs. (One tablespoon DRYCO supplies 31½ calories.)

DRYCO is made from spray-dried, superior quality whole milk and skim milk. It supplies 2500 U.S.P. units of vitamin A and 400 U.S.P. units of vitamin D per reconstituted quart. For information, write Borden's Prescription Products Division, 350 Madison Ave., New York 17, New York.

# STAYING POWER

Aggressive little atom of American bird-life, the beautiful Humming-bird flies so fast that the eye can scarcely follow. It operates its wings with such incredible power and speed that it is enabled to stand still—literally poised in air—as it gleans the nectar of flowers.

Similarly, the ability to remain "poised" over painful areas is attributed to small quantities of EUCUPIN, the local anesthetic-analgesic agent. Like the Humming-bird, Eucupin possesses a remarkable kind of *staying power*—the kind that controls pain for longer periods than any other agent, the effect lasting for hours and even for days.

Eucupin has been especially formulated for particular indications. They are described in a literature booklet, which, together with samples, is available to physicians on request. Please indicate form desired.

*Supply:* Aqueous and oil solutions for infiltration; ointment and suppositories; tablets for solutions to be applied topically.

## E U C U P I N

# Secondary Anemia

and

## Nutritional Failure

It is now quite generally accepted that in simple secondary anemia no hematinic other than iron is required for its correction. In many instances, however, anemia is accompanied by other signs of nutritional failure. Most frequently encountered is deficiency of the Vitamin B Complex.

In such cases Hebulon\* Capsules (Squibb Liver Extract, Ferrous Sulfate and Vitamin B<sub>1</sub>) offer not only an effective dose of exsic-

cated ferrous sulfate, but supply, in addition, 50 U.S.P. units of Vitamin B<sub>1</sub> and liver extract derived from 16 Gm. fresh liver. The capsules thus provide a convenient means of supplying not only iron, but B complex factor vitamins and hemoglobin-building substances contained in liver extract, which have been shown to be frequently needed in cases of nutritional failure.

Hebulon is supplied in bottles of 100, 500 and 1000 capsules.

**Chemical Combination Enables**

**SAFE AND**

**SIMPLIFIED THERAPY**

**in Urinary Infections**

Mandelamine by combining in a single medication the recognized effectiveness of mandelic acid as an acidifying agent and the efficiency of methenamine as a bactericidal agent offers the physician a safe and simplified method of treatment for urinary infections.

Gastro intestinal disturbances so common with other urinary antiseptics are virtually eliminated when Mandelamine is used. It is especially valuable in the treatment of pyelitis of pregnancy where its easy toleration does much to avoid aggravation of the nausea and vomiting often associated with the gestatory period. Other conditions for which Mandelamine is indicated are pyelonephritis, cystitis, prostatitis and the infection accompanying renal calculi.

In addition the course of administration with Mandelamine is relatively simple inasmuch as accessory acidification of the urine, constant checking of the urinary pH and the restriction of diet and fluid intake are generally unnecessary.

We suggest that you try Mandelamine in your practice so that you may observe its many advantages both to you and to the patient.

Supplied in enteric coated tablets of 0.25 Gm. each in packages of 120, 500 and 1000.

### **"Gone, But Not Forgotten"**

At the June meeting of the Council of the Medical Society of the State of New York, the resignation of Dr Joseph Lawrence, Executive Officer of the Society, was accepted with regret. Dr Lawrence resigned to accept the offer of the A M A to organize, develop, and operate the office of the Council on Medical Service and Public Relations of the A M A located at 1835 Eye Street, N W Washington, D C

"The Washington office of the Council was opened on April 3, 1944, at 1835 Eye Street, N W. Dr Joseph S Lawrence, Executive Officer of the Medical Society of the State of New York, was secured as a consultant and the development of the office placed under his direction. Reactions to this office have been favorable. Much needs to be done in organizing the states to cooperate with the office. Each state should designate a representative who will be the contact man with the Washington office so that information may be promptly circulated through the proper channels. Conferences with the states should be held at intervals to insure maximum efficiency in functioning. Two such conferences have already been held with the New England States and New Jersey. On June 11 another conference was held with other states here in Chicago. These conferences should be held from time to time in the future. Hence, the Council recommends that

the proper organization of the Washington office should consist of a full time director, subject to the Council, that there should be a field agent whose duties it shall be to maintain personal contact with state associations and keep them informed of the activities of the Council, such clerical help as may be necessary, and, eventually, a legal adviser, who at first will be on a part-time basis. There will be close collaboration between the Washington office and the Bureau of Legal Medicine and Legislation.

"The Council realizes that it has been criticized because it has moved slowly with reference to the Washington office. We feel that it has been most important to move slowly so that anything done would not have to be undone. The matter is now on a solid basis which will result in a constructive program and redound to the credit and benefit of the Association. One hasty action might well have set us back years.

"The bulletins issued by the Council have been well received, but they can be improved on. When the Washington office is functioning with a full-time staff, great improvement can and will be made in them.

"The Council regrets to announce that Dr G Lombard Kelly, who has been secretary since January 1, feels that he cannot continue after July 1.

Dr Lawrence has functioned as consultant most successfully since April, and his long experience as Executive Officer of this So-

ciety has fitted him for the work in Washington as no other physician to our knowledge has been prepared in the entire country. His, so to speak, resident and outpatient familiarity with the medical profession on the one hand, and legislators on the other, together with his own genial personality and acumen should assure the success of the Washington office from the start. But he must be supported, in all fairness.

We are in agreement with the A.M.A. Council on Medical Service and Public Relations<sup>1</sup> that to move slowly is perhaps to move wisely. But caution can be overdone, over-emphasized, too long drawn out. Events are on the move. Every facility for streamlined action should be afforded the Washington office, as of course it will be, since the A.M.A. has the resources and now has the best-trained man available to put those resources to productive work.

Dr. Lawrence is to be congratulated, that he will presumably have the backing in the national organization of Dr. Louis H. Bauer,<sup>2</sup> newly elected Trustee of the A.M.A., and Dr. Thomas A. McGoldrick,<sup>3</sup> member of the Council on Medical Service and Public Relations. He will need all the counsel and help he can get in this pioneering work.

The heartiest congratulations of the members of the Medical Society of the State of New York accompany Dr. Lawrence in his new field of endeavor. We shall miss him at the Council and District Branch meetings and at the sessions of the county secretaries and the Legislative Committee. As the Scots say: nothing is lost that a friend gets. *And American medicine surely needs a friend in Washington.*

## Poliomyelitis

Changes of great interest and importance to physicians in the state have been made with respect to quarantine regulations affecting cases of anterior poliomyelitis and meningitis. All physicians are hereby urged to read carefully the July 17 issue of *Health News*<sup>1</sup> and its supplement in which these changes are published in detail by the New York State Department of Health.

So much of Regulation 15 as applies is herewith reprinted:

Regulation 15. Persons suffering from chicken-pox, bacillary dysentery, measles,\* *meningococcus meningitis or meningococcemia (septicemia)*, ophthalmia neonatorum, pneumonia, *poliomyelitis*, epidemic or streptococcus (septic) sore throat, typhoid and paratyphoid fever to be isolated. Whenever a case of one of the diseases mentioned in this regulation comes to the attention of the health officer, he shall establish and maintain isolation of such case for the period specified herein; when isolation on the premises is impracticable, the health officer may cause the removal of the patient to a suitable hospital... *Poliomyelitis: until end of the febrile stage.* Epidemic or streptococcus (septic) sore throat: until recovery. *Meningococcus meningitis or meningococcemia (septicemia): until end of the febrile stage.*

This change in Regulation 15 was made by the New York State Department of

Health on the unanimous recommendation of the Advisory Group on Poliomyelitis<sup>2</sup> following its meeting on June 7, 1944, and after careful review of all available evidence.

In brief, the recommendations of this group were:

1. That all patients in whom a diagnosis of anterior poliomyelitis is suspected should be cared for in a hospital and that these patients may be safely admitted to the general wards but that it might be desirable to separate the patients in special wards for ease in handling.

2. That it be recommended to the Public Health Council of New York State and the Board of Health of New York City that quarantine procedures in hospitals be eliminated but that concurrent disinfection of all excretions be continued.

3. That all patients should be treated whenever possible under the combined supervision of the pediatrician, orthopaedic surgeon, and specialist in physical medicine, and that during the acute stage the patient should be kept at complete rest....

4. A complete physical examination should be made to determine the residual muscle weakness or paralysis as soon as the

\* Matter in italics is new; matter in brackets is deleted.

patient's general condition permits and local muscle pain or soreness has subsided. . . .<sup>3</sup>

### Says *Health News*:

"The sulfonamide drugs have been remarkably effective in curing illness due to infection with meningococcus and in promptly eliminating the inciting micro-organism from the nose and throat secretions. Isolation of the patient after he has recovered and quarantine of household contacts have not been shown to be of sufficient value in control of the disease to warrant the inconvenience to the patient and his family. Likewise, isolation of the patient after recovery and quarantine of the household contacts have been ineffective in the control of poliomyelitis, in which the epidemiology is similar. Immediate isolation of every patient who presents evidence of acute illness, regardless of its nature and before as well as after diagnosis is made, would be of greater value in the prevention of spread of most communicable disease.

The Public Health Council, at its meeting on June 27, amended Chapter II, Regulations 15 and 17, of the Sanitary Code on the basis of the foregoing considerations. Essentially identical changes were made July 11 by the New York City Board of Health in the city Code."

"Health Commissioner Ernest L. Stebbins recently released figures," says the *Journal of the Medical Society of the County of New York*, "which indicate that up to the present (July 22) the incidence of poliomyelitis. . . is about normal for the season. . . ."

Upstate New York, however, is not quite as normal. The changes in quarantine regulations will therefore be of more immediate interest and value to physicians in the suburban and rural districts. Especially is this true in areas in which large quantities of war and other materials are being produced. Emphasis is placed upon early, adequate, and constructive treatment by the action of the Advisory Council and the changes in the Health Regulations, rather than upon apparently relatively ineffective quarantine measures. Says Dr. James E. Perkins, Director, Division of Communicable Diseases, State Health Department, in part,

"I think that the steps taken by the Public Health Council in modifying the isolation and quarantine regulations was very definitely a step forward, and one which results in requirements more in accord with present scientific knowledge. Nevertheless, in the presence of an epidemic of poliomyelitis, it is possible that an adverse reaction may occur on the part of the public, particularly if, when they inquire of their family physician, they do not get a satisfactory answer. I think it is important, therefore, to have the physicians throughout the State aware of these changes, and that the reason for the changes

myelitis infection and thus can never come under governmental restriction although perfectly capable of spreading the infection, it is possible to control the spread of the infection through government regulation. Emphasis should be where it belongs; namely, on proper and adequate treatment of the occasional, relatively rare individual who acquires the paralyzing form of the disease. Any comments along this line in the *JOURNAL*, editorially or otherwise, would materially assist us in this program. . . ."

The *JOURNAL* takes this early opportunity to present to the physicians of the state the reasons for the changes in the regulations governing the isolation of cases of anterior poliomyelitis and meningitis and asks the cooperation of all physicians in familiarizing themselves with the recommendations of the Advisory Council.

<sup>1</sup> *Health News* and Supplement, 21: 29 and 8-29 (July 17) 1944. This issue has been sent by the New York State Department of Health to every physician in the State. Additional copies may be had by writing to New York State Department of Health, Albany, New York.

<sup>2</sup> The Advisory Group includes the following members: Dr. Alan DeForest Smith, professor of orthopaedic surgery, College of Physicians and Surgeons, Columbia University; Dr. Philip Duncan Wilson, chief orthopaedist, Hospital of Special Surgery, New York City; Dr. William Benham Snow, associate professor of medicine, College of Physicians and Surgeons, Columbia University; Dr. James L. Wilson, professor of pediatrics, New York University; Dr. R. Plato Schwartz, associate professor of orthopaedic surgery, University of Chicago.

<sup>3</sup> *Health News*, July 17, 1944. Chairman, Council Committee on Public Health and Education, Medical Society of the State of New York.

## Mass Chemoprophylaxis

One of the major medical problems in military camps and in institutions is the prevention of epidemics. When serious ailments, such as meningococcus meningitis, appear on the scene, it is of the utmost importance to promptly stop the spread of the disease. The solution lies not only in the removal and the speedy cure of the

afflicted but in the effective extinction of the offending organisms which are harbored in the selective tissues of the contacts. The problem, then, is to prevent the contacts and potential carriers from becoming active carriers. Sulfonamide prophylaxis on a massive scale has been successful as a solution to this problem.<sup>1</sup>

In an Army camp infected with meningococcus meningitis, isolation of the organization in which the case appeared was immediately instituted, and cultures were taken of the nasopharynges of all contacts. The carrier rate was found to vary from 12.5 per cent to 42.3 per cent. Quarantine was not removed until the carriers were isolated. The latter were given 2 Gm. of sulfadiazine daily for two days, and then 1 Gm. for two days. No ill effects were observed in 897 carriers so treated. As a result of this course of prophylaxis all but 30 carriers were freed of meningococci. These were treated with sulfanilamide in the same dosage. All the remaining carriers but one revealed negative cultures after the second course. He was treated with sulfathiazole solutions in the nasopharynx, after which his culture became negative. Contacts were permitted to return to duty when two cultures were negative.

Since time and facilities do not always permit bacteriologic study of the entire personnel, 6 Gm. of sulfadiazine were routinely administered to everyone in the camp. No ill effects were observed, and there was no interference with normal activities. No case of meningitis had appeared seven days after the start of this mass therapy. After one month 928 showed the remarkably low carrier rate of  $\frac{3}{4}$  per cent. Such data may be interpreted as demonstrating the

virtual cure of meningitis carriers, for similar data have been reported from other quarters.<sup>2</sup>

Mass sulfonamide prophylaxis against other bacterial diseases has been investigated with further encouraging data. Thus, outbreaks of scarlet fever in a naval station,<sup>3</sup> streptococcus respiratory infections,<sup>4</sup> and dysentery epidemics<sup>5</sup> in institutions have been limited and controlled by judicious and appropriate mass sulfonamide administration. The use of these large groups for the purpose of diminishing the carrier rate is thus proved to be not only feasible and harmless but gratifyingly effective. The discovery of infections amenable to sulfa therapy in an institution, camp, or other site of mobilization would seem to call for study and treatment of the contacts in order to prevent or delimit the carriers which normally follow. It is these carriers who are responsible for the spread of epidemics which we now have good reason to believe can be stopped in their tracks by mass prophylaxis.

### Competition for Prize Essays

The Merrit H. Cash Prize and the Lucien Howe Prize will be open for competition at the next Annual Meeting of the Medical Society of the State of New York.

The Lucien Howe Prize of \$100 will be presented for the best original contribution on some branch of surgery, preferably ophthalmology. The author need not be a member of the Medical Society of the State of New York.

The Merrit H. Cash Prize of \$100 will be given to the author of the best original essay on some medical or surgical subject. Competition is limited to the members of the Medical Society of the State of New York, who at the time of the competition are residents of New York State.

All essays must be presented not later than February 1, 1945, and sent to the Chairman of the Committee on Prize Essays of the Medical Society of the State of New York, 292 Madison Avenue, New York 17, New York.

Committee on Prize Essays

# THE MANAGEMENT OF WAR AMPUTATIONS IN A GENERAL HOSPITAL

RUFUS H. ALLDREDGE, Capt., (MC), AUS

THE problems confronting the orthopaedic surgeon on an amputation service in a general hospital are many and complex during war. The work consists chiefly of handling war casualties on whom the guillotine amputation has been performed six to twelve weeks previous to admission. Treatment is continued until the patient is properly fitted with a prosthesis and discharged from the hospital. A few primary amputations of the open and closed types are performed on the service. Some patients who have previously had closed amputations are admitted for further after-care and fitting or for care of complications resulting from the closed amputation. Opportunity is therefore presented for observation of the results of (1) the guillotine amputation, (2) the closed amputation, and (3) the open amputation with flaps secondarily closed.

Since the management of war amputations in a general hospital consists chiefly of handling guillotine amputations done under war conditions, the primary purpose of this presentation is to re-emphasize the value of the guillotine amputation and to summarize the important points necessary for the most successful immediate and late after care of these cases.

## Types of Cases

The type of case most commonly seen is the guillotine amputation in various stages. Generally, the cases fall into one of three groups as follows:

1. Completely healed stumps ready for fitting
2. Completely healed or unhealed clean stumps ready for revision or reamputation
3. Complicated cases showing osteomyelitis with or without sequestrum, chronic soft-tissue infection, extensive dermatitis, retraction of skin and soft tissues, and joint contractures. A patient may have one or all of these complications usually the direct result of improper operative technique and after-care.

Although closed primary amputations and secondary closure of stumps left with open flaps are inadvisable under war conditions, a number of these have been seen on the service. About half of these cases apparently healed with infection, but the stumps frequently are edematous

and painful. The remaining cases definitely have complications due chiefly to infection.

## Routine Procedure upon Admission to the Hospital

Patients may be admitted to the hospital either singly or in large numbers, and this admission may take place from two weeks to a year or more following amputation. The average patient, however, is admitted six to twelve weeks after operation. The routine care of the patient upon admission to the hospital consists, first of all, of a check-up on his general physical condition and routine laboratory work. It must be remembered that under modern war circumstances amputees frequently have multiple disabling conditions such as compound fractures, eye, ear, dental, chest, abdominal, neurosurgic, and urologic injuries. Some of them have double major amputations. The local condition of the stump is carefully determined and the amount and type of traction that the patient has had following amputation is ascertained. All open wounds are routinely cultured for aerobes and anaerobes, and cultures are repeated at intervals during the patient's preoperative treatment. The stumps and other injuries are x-rayed and patients are measured for the Army adjustable fiber prosthesis and for low-quarter shoes. This is done as soon after admission to the hospital as possible, preferably at the same time that the wounds are examined and cultured.

After these measures have been carried out, the actual treatment of the patient begins. This consists of systemic as well as local treatment. Most of the upper extremity amputations and many of those of the lower extremity may be ambulatory until they are ready for operation to fashion the final stump. Others require bed treatment. Weight loss and secondary anemia are treated by high vitamin, high caloric diets, and by vitamin and iron therapy and transfusions. Some chronically infected patients are treated with penicillin or sulfonamides.

Most of the patients who are not ready for surgery because of retracted skin or insufficient healing of a guillotine amputation are placed in skin traction with skin glue and stockinette. Those who do not need traction are referred to the physiotherapy department for exercises, wrapping of the stump with ace bandages, whirlpool, and ultraviolet light. Proper wrapping of the stump and active exercises of the involved ex-

Read by invitation at the Annual Meeting of the Medical Society of the State of New York, New York City, May 10, 1944.

FIG 1 A—Bilateral guillotine amputation of forearms performed three months earlier. Injury was the result of explosion of a detonator in patient's hands. Traction was never applied, skin retracted and bone sequestered. If traction had been properly used the necessity of revision might have been obviated.

B—Same as Fig. 1A five weeks after revision was done with the use of penicillin. Stumps completely healed, painless, and ready for fitting with prostheses. Patient's mental attitude greatly improved.

tremity are the most valuable measures which physiotherapy has to offer in the treatment of these cases. Patients who have undergone amputation of an upper extremity are referred to the occupational therapy department for instruction in the use of the normal extremity and for understudy of other patients using an upper extremity prosthesis.

### Complications of the Guillotine Amputation

The guillotine amputation has been described in all its aspects by Kirk and McKeever<sup>1</sup> recently, and all who are interested are referred to their article. It is only when the proper technic of the operation and of the after-care is followed that the best results are obtained. Patients who have been properly handled have been received in excellent general condition and their stumps have developed few complications. The

most common causes of poor results from the use of the guillotine amputation are: (1) improper surgical technic, and (2) inadequate after-care.

If the amputation is performed too high or at the site of election it does not leave so good a stump for refashioning as does an amputation performed at the lowest possible level. It is better for reamputation to be done later at a higher level than to have a stump guillotined too short or at the site of election. If too much soft tissue is left distal to the bone end, proper drainage does not take place and complications may arise from lack of proper drainage. Closure of the stump too early after operation may give the same undesirable result. Unnecessary stripping or removal of periosteum causes sequestra and exostoses.

The lack of proper after-care of the guillotine stump is the most common and most serious mistake made. If skin traction is not applied properly and maintained constantly even when a patient is being moved, the skin and other soft

<sup>1</sup> Kirk, Norman T., and McKeever, F. M.: J A M.A. 124: 1030 (April 8) 1944.

FIG. 2 A—Healed guillotine amputation of the thigh. B—Protruding femur stump. When the bone is not removed or callus grafts, and closure of normal skin over the protruding bone without shortening. Penicillin used pre- and postoperatively.

tissues retract the bone ends protrude the stump becomes painful, and flexion contractures develop. The bone ends may later undergo sequestration and various forms of infection occur in the stump. It follows therefore that neglect in the immediate after care of the guillotine stump results in poor general condition of the patient as well as delay and difficulty in obtaining a good final stump.

#### Definitive Treatment of the Guillotine Stump

The treatment of the guillotine amputation stumps must be individualized to a great extent, as they vary considerably in many respects. It is possible to fit many guillotined arm, forearm and thigh stumps without any further surgery. More often, however, the guillotine stump needs

some further type of operation to make the best possible stump for the application and use of an artificial limb. The proper time at which the final operation is done, and the type of operation performed depend upon many factors including the condition and appearance of the stump as well as the x-ray findings and the type of organisms present. If (1) no gross infection is present, (2) x-rays show no evidence of active bone infection or sequestra, (3) good skin is well down over the end of the stump, (4) there is little or no edema, and (5) the wound is clean and granulating then the stump is said to be physically ready for the final operation. It is very important, however, that the type of organisms present in the wound be determined in every instance prior to operation. The most common organisms found in the stumps are the diphtheroid

organisms, *Pseudomonas aeruginosa*, *Bacillus proteus*, and various types of streptococci and staphylococci. Patients are given sulfonamide or penicillin therapy pre- and postoperatively, depending upon the organisms present in repeated cultures and smears from the wound. Local treatment of the wound may be necessary to clear it of organisms not susceptible to chemotherapy.

These measures include whirlpool baths, ultra-violet light, chlorinated solutions and oils, 4 per cent chloral hydrate for *B. proteus*, and proflavin 1:1000 for *Ps. aeruginosa*. Local dressings with Dakin's solution or pectin jelly clean odorous stumps with exudates in a very short time.

Reamputation at a higher level when this is permissible may generally be done at or near the

FIG. 9. A—Below-knee guillotine amputation with retracted soft parts, protruding bone stumps, and sequestration. B—Same two weeks after supracondylar tendoplasty amputation. Penicillin used pre- and postoperatively.

stump end. A simple revision operation and closure of the stump end with good skin is performed when no further shortening is desired. Reamputation is performed if the remaining stump is longer than necessary for the best function. If the stump is too short to function well with a prosthesis, reamputation above the joint is also indicated for better results.

Osteomyelitis with sequestration should be surgically treated by adequate incision, sequestrectomy, dressing the stump end open, splinting, infrequent dressings, and pre- and postoperative sulfonamide or penicillin therapy. Healing occurs fairly promptly, much more quickly than in other types of osteomyelitis.

Stumps which have retracted skin and those in which conservation of length is essential are kept in traction as long as the skin continues to lengthen and until the wound is clean, before revision is attempted. All guillotine amputations are far better handled by continued traction than by attempts at skin grafting. If applied to lower extremity stumps, skin grafts will eventually require removal, as they will almost always break down from the use of a prosthesis. Operative procedures for removal of skin grafts are far more extensive and the results less satisfactory than the use of continued traction followed by revision and closure of the stump. If an amputee

requires a skin graft for any reason, the graft should never be taken from the skin of the amputation stump.

### Postoperative Care

The essential points to be followed in the postoperative care are drainage of the wound, immobilization, elevation, and continued sulfonamide or penicillin therapy. All stumps are drained with a rubber dam drain in each end of the wound. The drains are removed at the end of two to five days. Below-knee and forearm stumps are best immobilized by the use of a sugar-tong plaster splint applied over padding with an ace bandage wrapped snugly over the dressing. Skin traction is used on stumps in which swelling may cause tension on the sutures. Arm stumps are best immobilized on a pillow, and thigh stumps by a spica bandage or by traction. The limb is kept elevated, and patients, except those who have forearm stumps, are never allowed to get up until the sutures have been removed. Occasionally, when circulation is questionable, novocaine sympathetic block or low caudal anesthesia is given postoperatively. Preoperative sympathectomy should be carefully considered in all patients who have poor circulation.

The stump is kept well wrapped with ace bandages from the time of the first postoperative dress-

FIG. 10. A—Guillotine disarticulation of knee performed for compound fracture of the upper third of the tibia and fibula and total loss of circulation. This is the appearance of the stump four weeks postoperatively. Nearly ready for operation. Disarticulation of the knee is always preferable to amputation higher up.  
B—Same three weeks after supracondylar tendoplastic amputation for full end-bearing. Done with penicillin.

ing until the prosthesis is applied. It is then kept wrapped for three to six months, when the limb is not actually being used. When the stump is well healed, active exercises are begun and kept up indefinitely. Massage may be useful if properly given, but may be definitely harmful if not administered with the greatest care and under proper supervision.

### Prosthesis

The patient's limb is ordered from actual measurements upon admission to the hospital and is usually on hand in the limb shop, ready and waiting, by the time the stump has healed. Except in cases of full ischial-bearing thigh stumps, a plaster mold of the stump is taken, and a leather socket is made to fit the individual stump. The prosthesis can be applied in less

than a week after the stump is ready for fitting.

The Army prosthesis is made of fiber, except for the leather socket. The limb is adjustable for shrinkage of the stump which takes place as it is worn. Both a split hook and a hand are provided for arm amputees, who are properly instructed in their use in the occupational therapy department. The department of physiotherapy conducts walking classes in which patients with lower extremity amputations are first taught balancing exercises, and then how to walk with their prostheses. When the patient reaches a point where he is properly fitted and shrinkage is at a standstill, he is given a final check-up and proper adjustments are made before he is discharged from the hospital. He may use the adjustable fiber limb for an indefinite period of time.

# REPORT OF EIGHTY-FIVE FENESTRATION OPERATIONS FOR OTOSCLEROSIS

J. MORRISSET SMITH, M.D., New York City

THIS is the second report of my surgical experiences with the fenestration operation for otosclerosis. The first report, in the *Archives of Otolaryngology*, February, 1943, consisted of thirty-two operations. This article includes fifty-three additional operations.

## Technic

In order that a better understanding of this report may be had, a very brief description of the technic follows.

An adequate exposure of the cortex is made through an eudaural incision. This is definitely the best approach, because of the facility with which the bleeding is controlled. The mastoid cortex is then removed and the entire cellular contents of the mastoid cavity is exenterated to the bony plate covering the dura and lateral sinus in the posterior fossa and to the dural plate in the middle fossa. This step is necessary because it shortens the after-treatment and promotes rapid healing and epidermatization of the operative cavity. The horizontal and posterior semicircular canals are exposed and thoroughly delineated. Then the dense bone forming the external attic wall is removed, skeletonizing and allowing the thin bone forming the roof of the middle ear and the posterior wall to remain in position temporarily. The removal of the external attic wall is carried forward until there is a complete exposure of the incus and the head of the malleus. It is also removed above, exposing the bony plate in the floor of the fossa. A thin elevator is then used to separate the cutaneous membrane lining the canal from the skeletonized wall. This wall is then carefully removed through the annulus, preserving the drum and lining membrane intact. The incus is removed together with the head of the malleus, the facial ridge is lowered, and a plastic skin flap is constructed to cover the fistula and seal off the epi-tympanic space. The fistula is then made, the flap placed in position, and the dressing applied.

It was pointed out in the first report that this is essentially an operation for conduction deafness and that it was impossible to differentiate the otosclerosis cases from other types of the so-called catarrhal deafness. Since it is not possible to make an absolute diagnosis of otosclerosis without a histologic examination, the term "clinical otosclerosis" will be used to des-

ignate the types of conductive deafness discussed in this article.

For those of you who are not familiar with this problem, it may be briefly stated that clinical otosclerosis is characterized by the formation of new bone in the otic capsule, or the dense ivory bone forming the outer wall of the internal ear. These bone deposits may take place without impairment of hearing. When they involve the bone surrounding the region of the oval window, the footplate of the stapes becomes firmly fixed, blocking the pathway for air-borne sounds to the perilymph and endolymph of the internal ear, causing a conduction deafness. The fenestration operation makes it possible to restore practical hearing through the construction of a new pathway for air-borne sounds to the circulating fluids of the internal ear, making what is in effect a new oval window directly above the old one with only the facial nerve separating the two windows; thus the endolymph and perilymph are again mobilized for the transmission of air-borne sound to the organ of Corti.

The results in the first thirty-two cases were approximately one-third successful. They have greatly improved in the fifty-three additional cases.

The marked improvement in the results dates back to the new location of the fistula. In the first eighteen operations of the total of eighty-five, the fistula was made over the length of the external semicircular canal posterior to the ampullated end, with the head of the malleus removed and the incus in its normal position. In the rest of the series, sixty-seven in number, the fistula was moved forward over the dome of the vestibule anterior to the ampullated end of the horizontal semicircular canal, with the head of the malleus and the incus removed. The results immediately improved. Placing the fistula anterior to the ampullated end of the semicircular canal allows it to be made wider. The bone forming the dome of the vestibule is much thinner and there is no bone at the bottom of the fistula as there was when it was made over the length of the external semicircular canal. The removal of the incus along with the head of the malleus permits the thin part of Shrapnell's membrane to be placed over the fistula. These factors together have greatly reduced the number of closures of the fistula and have materially contributed to the improved results. The ideal indication for the fenestration operation is a

typical clinical otosclerosis syndrome before there is a serious impairment of the auditory nerve. This would include an intact drum membrane, a drop in the hearing below the level of practical conversation, adequate bone conduction, a patent eustachian tube, and an absence of any evidence of a middle-ear or mastoid infection.

It will be noted that this modifies somewhat the indications set forth in the first report. An intact drum with a firmly healed perforation, a small calcareous deposit, or a retraction or loss of color of the drum does not mean that a successful result may not be obtained. Likewise, an old infection of the middle ear and mastoid which has long since subsided with an intact drum, does not prevent a good result. These findings may then be considered within normal limits for this work.

The one fact requiring special emphasis is that in a vast majority of the cases of clinical otosclerosis there is a gradual loss of hearing extending over a considerable period of time before there is a serious impairment of nerve function. It is during this stage that the operation offers the best chance for a successful and lasting result. If allowed to continue uninterrupted, the loss of nerve function will reach a point where the individual cannot be helped by the operation.

It is important that the large number of people afflicted with this disease be informed of the possibilities of surgical relief while there is still sufficient nerve function remaining to convey the sounds to the internal ear.

There has been considerable criticism of this work because of the closure of the fistula in some of the cases. There is no way, at the present time, to guarantee that it will not close; however, in properly selected cases—that is, those with clinical otosclerosis with a sufficient reservoir of nerve function—there is an excellent chance of securing a successful and lasting result.

What are the prospects without operation? There is a gradual and progressive loss of hearing followed by a slow deterioration and loss of nerve function, resulting finally in a severe or total deafness with no prospects of help from an operation, hearing aid, or from any other source.

What does the operation require of the patient? With the correct indications and in the hands of a skillful and properly trained operator there is a minimum risk from the standpoint of danger and a comparatively brief period of convalescence. In the early stages of this work, there was often a very long and tedious treatment necessary, due largely to the fact that it was not thought necessary to completely exenterate all the cells of the mastoid. Secondary infections occurred in the remaining cells and

sometimes months were required to complete the after-treatment. Experience has largely corrected this. The mastoid cells are completely removed and the secondary infections have been definitely curtailed or completely controlled. It requires approximately twelve days' hospitalization, followed by a comparatively short period of postoperative local treatment while the cavity dermatizes and becomes completely dry.

There is considerable dizziness and discomfort without pain immediately following the operation. This rapidly improves following the first complete dressing, usually done on the fifth day.

### Mixed Cases

The next problem, one which is very perplexing and about which there is much to be learned, is the mixed case, or the one with both hearing impairment and partially damaged nerve. How far should the impairment progress before the operation is contraindicated? We are greatly handicapped by the lack of an accurate method of testing the residual nerve function. For instance, I have just examined a patient with a hearing loss of approximately 50 per cent in both ears by air as shown by the audiometer and no response to any of the tuning forks in either ear, indicating a complete absence of bone conduction. How can this amount of hearing by air be explained, if bone conduction is an accurate test of nerve function? This phase of the work offers a tremendous field for further research.

If the impairment of nerve function is not too marked, there is still a chance of checking the progress of the disease and maintaining serviceable hearing for the individual. The fact that the partially damaged nerve diminishes the prospect for a successful result should be fully explained, and the patient should be given the chance the operation still offers if it is desired.

Lempert<sup>2</sup> states that a result should be considered wholly successful if the hearing is restored to the practical level for conversation; that is, around the 25-decibel level or better, with which opinion I concurred in my first report. However, if an individual with a progressive clinical otosclerosis could have the disease arrested and maintained at the 30- or even 40-decibel level, this would be a real service to that particular individual, and is a thought well worth considering in the patients with a partial impairment of nerve function.

### Advanced Cases

This group includes the patients with a marked loss in both air and bone conduction, as well as the ones diagnosed as having nerve deafness.

Lempert reported some successful results with

this form of deafness I operated upon six patients in this whole series, with air and bone conduction showing a marked loss, after carefully explaining that the prospects of a successful result were not good and securing the patients' full consent under those circumstances. There were no successful results in any of them. In two of them, there was definite loss in the slight function remaining. It should be noted that there was no practical function present in this type of deafness, therefore, the patient had little to lose by trying for a result on the worst ear. A successful result in this type of disease could be explained only by the fact that there was a concealed reservoir of nerve function present before operation.

There seems to be no known method, at this time, of successfully testing and determining the presence of this hidden reserve function prior to the fenestration. From my brief experience with this phase of the work, there is a very definite chance of further retrogression or loss of function following an operation in these cases. This should be carefully explained to the patient, if it is attempted.

### Secondary Operations

Two of the original patients with the incus in position and the fistula over the length of the semicircular canal were reoperated upon. In both of them, the fistula was completely covered with new bone. In each one the bone was removed and the hearing was restored. In one it remained and has continued open with good practical hearing, now almost four years since the original fenestration. The other one closed and hearing returned to its preoperative level.

One of the novofenestra was revised. A new lid of bone was found over the fistula, attached to the membranous labyrinth in the dome of the vestibule. It was removed with infinite care and great difficulty, without seriously injuring the membranous labyrinth, the hearing improved, and part of the hearing gain has been maintained more than a year, as well as checking the progress of otosclerosis.

The hearing recessions in some of the fenestrations over the dome of the vestibule are due to a fibrosis as well as to osteogenesis.

If there is a well-defined new lid of bone over the fistula, as in the one just described, there is a chance of carefully removing it and securing a successful result. If there is a fibrosis with adhesions to a membranous labyrinth, there is too much danger of a dead labyrinth to justify further attempts to remove the adhesions.

### Comments

These eighty-five patients were all operated upon at the New York Eye and Ear Infirmary.

The audiograms, in the early cases, were made by house officers, the rest, pre- and postoperative, were made by the technician at the hospital and are all on record at that institution.

There were no facial paralysis, meningitis, diffuse labyrinthitis, deaths, or intracranial complications in this series.

Excluding the six operations performed on the cases with serious nerve impairment in an effort to improve them and to further determine the merits of this procedure, there was only one instance in which the hearing was made definitely worse. This man had approximately 50 per cent loss of hearing with excellent bone conduction, a patent eustachian tube, and an intact ear drum. Each step of the technic was completed in a satisfactory manner at the time of the operation and an excellent fistula was established. There was no unusual postoperative labyrinthine reaction. Six months after operation the loss of hearing showed only a slight improvement. There was, at that time, an active labyrinth with very good bone conduction.

I am totally unable to explain the findings in this case. In view of the active labyrinth and good bone conduction, there should be a chance to improve the hearing. I expect to operate on the patient again at a later date.

The closure of the fistula by osteogenesis or fibrosis constitutes the paramount problem in this work and should be first on the research list.

The establishment of the fistula is necessarily the most important and difficult step of the operation. After doing a number of them, one naturally does a great deal of thinking and speculating in an effort to determine what may be done at the time the fistula is made that may improve the results and lessen the number of closures. The fistula is made with a small dental bur and a Zeiss lens which magnifies approximately two and one half times. As I think back over the fistulas I have made, it seems to me the most successful were the ones in which the bone was removed and the endosteum powdered and removed without disturbing the translucent outer wall of the membranous labyrinth. It should be remembered that part of this step is practically microscopic and cannot be accomplished with the same degree of exactness in every case. This is largely theoretic at this time, however, if the magnification could be enlarged and the serrations in the bur made finer so that the bone removal could be stopped at the same point in each case, the results might be definitely improved.

If the hearing is successfully maintained after several months, the results are apt to be permanent.

Why there will be bone regeneration and closure in some and a permanent fistula with lasting

FIG. 1. Case 1. Lower line—hearing curve before operation, July, 1940. Upper line—hearing curve approximately four years after operation. Note that hearing has been maintained for almost four years.  
FIG. 2. Case 2. Lower line—hearing curve before operation, September, 1940. Upper line—hearing curve three years, eight months after operation.

results in others, when the technic is apparently the same, is still the chief problem.

I began this work in the summer of 1940 and have some cases that have successfully maintained their improved hearing almost four years. Lempert has some that have maintained their hearing improvement for more than six years.

In my experience, the ones that have successfully remained open after nine months or a year have consistently maintained the gain from that time to the present and there is every reason to believe that they will be permanent.

Lempert makes the very interesting observation that in all the histologic sections made of the

temporal bone, showing the presence of otosclerosis, none of them have ever shown an involvement of bone over the dome of the vestibule where the new fistula is made. This is an additional reason for assuming that results in the successful cases of several months' duration will be permanent.

I stated in my first report that this work is just beginning. This is still true.

The experience gained in the fifty-three additional operations reported in this article confirms several statements made in the first report. This is essentially an operation for conduction deafness; although good results are obtainable in

FIG. 3. Case 3. Lower line—hearing curve before original fenestration operation, March, 1941. Upper line—hearing curve three years, two months after operation. Note that improvement is of more than three years' duration.

FIG. 4. Case 4. Lower line—hearing curve before operation, January 28, 1942. Upper line—hearing curve two years, three months after operation. Note: Fistula visible to the naked eye.

Fig. 5. Case 5. Lower line—hearing curve before operation, November 11, 1942. Upper line—hearing

Fig. 6. Case 6. Lower line—hearing curve before operation, November 11, 1943. Upper line—hearing

many cases, it is not possible to guarantee results in any individual case.

There is definite danger in the hands of the untrained technician. The operation must first be taught on the cadaver and the necessary effort devoted to the correlation of the intricate steps comprising the technic before it is attempted on the living.

It opens a vast field for otologic research. There is much to be learned about the proper testing of the hearing as a whole, the estimation of damage done in the individual frequencies, and the correct measurement of residual nerve function. We should, with more experience, be better able to classify the different types of deaf-

ness and to make a more accurate prognosis before operation.

Cataract operations have been restoring sight for a long time. The fact that they are not all successful does not mean that the operation should be discarded and has not prevented it from restoring useful vision to many thousands of persons. In my opinion, the fenestration operation for deafness is capable of rendering the same service to humanity in properly selected cases. Failure to secure successful results in some of them will not prevent the procedure from rehabilitating the lives of many persons both socially and economically by restoring practical and lasting hearing to them.

Fig. 7. Case 7. Lower line—hearing curve before operation, December, 1943. Upper line—hearing curve five months after operation. History of otitis media. Note: Thin secondary membrane in ear operated upon.

Fig. 8. Case 8. Lower line—hearing curve before operation, December 12, 1943. Upper line—hearing curve four months after operation. Mother and father of patient deaf mutes. Note: operation at 9 years of age.

It may be employed from childhood, as evidenced by a little girl 9 years old, presented at this meeting, to a well-advanced age. Fifty-eight was the oldest in this series. An older age is compatible with this operation, providing the physical condition is satisfactory.

If the operation is not successful and the fistula closes, with the proper indications and technic, in the vast majority of cases the hearing will merely recede to its preoperative level.

This technic involves the complex anatomy of the mastoid process and the middle and internal ear, and while there is necessarily a minimum danger in any major surgical operation, the eighty-five cases reported in this article demonstrate that it may be performed without undue risk to the patient.

One important fact learned by experience in the after-treatment is well worth recording. In the early stages of this work I had a great deal of trouble with secondary infections in the mastoid cavities after operation, some of them being extremely persistent and difficult to control. At Lempert's suggestion, a 2 per cent aqueous solution of gentian violet was used to coat the interior of the operative cavity after the first dressing on the fifth day. It was used on the flap and drum and raw surfaces. This contributed greatly to the control of the secondary infection; however, I suddenly began noticing some small perforations in the drum membrane which had never occurred before. The perforations healed after use of the dye was discontinued. This dye is extremely penetrating and should not be used on the drum and should be kept away from the edges of the flap in the early stages of the after-treatment until the attic and middle-ear spaces are thoroughly sealed by granulations.

I wish again to extend credit to Lempert for his cooperation and for the tremendous impetus he has given to this important research by completing the one-stage technic and improving the location of the fistula, as well as constantly striving to improve the technic and results.

The question of the hearing aid versus fenestration naturally arises. There are many people definitely opposed to the use of a hearing aid, while others do not mind and are unquestionably benefited by its use, especially for a certain period of time.

The fact that is of vital importance to a patient with clinical otosclerosis is that it is a progressive disease and many of them reach a point where the hearing aid is completely useless, while a successful fenestration not only makes it possible to discard the hearing aid completely but restores useful hearing and checks the progress of otosclerosis.

## Case Reports and Presentations

There are six postoperative patients with their hearing records, before and after operation, present at this meeting for examination. They represent a cross section of this work from the time I began it in July, 1940 to May, 1944. The longest, in period of time, is of nearly four years' duration, the shortest four months'.

*Case 1.*—The patient, who is now 28, had an original fenestration in July, 1940. His hearing improved and then receded. A secondary operation was performed in June, 1941. The fistula was covered with new bone; this was removed and the hearing was restored and the gain has been maintained for nearly four years since the first operation.

*Case 2.*—The patient is 35. He had an original fenestration in September, 1940. He has a very active fistula and has excellent results. It is now three years and eight months since the fenestration.

*Case 3.*—The patient is 45 and underwent original fenestration in March, 1941. He has good hearing for all practical purposes. It is now three years and two months after operation.

*Case 4.*—The patient is 18, and had a fenestra Nov-ovalis made in January, 1942. The patient's hearing was so bad when he was 16 that he considered stopping school and taking up lip reading. The postoperative improvement in the hearing is remarkable. It is now two years and three months after operation. The patient finished school and has a clerical position. Note the fact that the fistula is visible with the naked eye.

*Case 5.*—The patient, who is 35, had a Nov-ovalis fenestra made in November, 1942. Note the marked improvement in the 2048 frequency one year and six months after operation. This results in excellent hearing for ordinary conversation.

*Case 6.*—A Nov-ovalis fenestra was made in July, 1943. There is a fine practical gain more than ten months after operation.

*Case 7.*—The patient is 33 and has a history of a double middle-ear infection at the age of 5. Examination showed a bullous thin secondary membrane covering a large perforation of the drum in the left ear, with the audiogram showing a 40-decibel loss in the 512 and 1024 frequencies and a 15-decibel loss in the 2048 frequency. The right ear showed a good-sized perforation of the drum occupying the lower and posterior quadrant, covered by a fairly thin secondary membrane. The audiogram showed a 60-decibel loss in the 512 frequency, 50 in the 1024 frequency, and a 30 decibel loss in the 2048 frequencies. I debated about operating because of the history of previous infection and the thin secondary membrane covering this perforation; I consented to operate after fully explaining the possibilities of the thin membrane's failing to hold, and gaining the patient's full consent. A fenestration (Nov-ovalis) was performed in the right ear. Operation disclosed a sclerotic bone with practically no cells. The incus and malleus were surrounded by granulations with no apparent infection. The granulations made me regret operating, but after

removing them with the mucus and the head of the malleus an excellent fistula was established. The audiogram shows a gain of from 60 to 25 decibels in the 512 frequency, from 55 to 25 in the 1024 frequency, and from 30 to 10 in the 2048 frequencies.

This case history is reported in detail to show that a previous infection does not contraindicate the operation providing the infection has completely subsided and the drum is strong enough to permit the removal of the mucus and the head of the malleus and still remain intact.

*Case 8*—This patient is 9 years old. This little girl's mother and father are both deaf mutes. The father's deafness resulted from meningitis at the age of 6.

The mother was born a deaf mute. Upon examination, the child's hearing was found to show about 35 per cent loss in both ears, with good bone conduction, intact drums, and no history of previous aural infection. Unfortunately, with both parents totally deaf and with her own impairment of hearing she had had no schooling and could talk very little and used the sign language of the deaf mutes. The fact that the mother and father are deaf mutes is probably a coincidence. A fenestration was performed on the right ear on January 5, 1944. Her hearing shows a marked improvement and is normal for all practical purposes. She has been in school for two months making excellent progress. This is the youngest patient by five years upon whom I have performed this operation, and I believe the youngest on record anywhere at this time. While more time has to elapse before the results can be considered permanent, it shows that this early age does not contraindicate the operation and emphasizes the importance of re-establishing a pathway for sound to the internal ear before serious damage to the nerve has occurred.

## Conclusions

The fenestration operation is a thoroughly established surgical procedure capable of restoring practical and lasting hearing in selected cases.

The eighty-five operations reported in this article without any complications or deaths prove that it may be performed without undue risk to the patient.

There is a definite danger in the hands of the untrained technician. The operation must first be taught on the cadaver and the necessary time and effort must be devoted to the correlation of the intricate steps comprising its technique before it is attempted on the living.

The successful fenestration operation not only restores practical hearing but also checks the progress of the otosclerosis.

This work represents a fine type of research and merits in every way the full support of the otologic profession.

## Discussion

Dr. James A. Babbitt, Philadelphia—It is a signal honor to be invited to discuss this careful review of such a large number of fenestration operations by the endaural route.

These are essentially radical operations, performed with nicety of technique which we have long associated with Dr. Smith's mastoid surgery.

It is nearly forty years since the first radical mastoidectomy by the endaural route was performed by the elder Theis in 1907. The story of its evolution and modifications during these years has been a fascinating one, linked with the names of the most famous otologists in Europe. Now, illustrious names from our own country are being added.

Why is this fenestration procedure so important? Simply because it fills a serious gap in our therapeutic regimen. America is awakening to the importance of bringing up the efficiency of its youth. Nothing more striking has occurred than the great interest which has swept the country in the detection and prevention of impaired hearing and vision. The Academy of Ophthalmology and Otolaryngology is endeavoring to stimulate throughout America uniform procedures for survey and detection of otologic and ophthalmic clinics for necessary treatment. In school children much can be done, but in adults and the soldier returning with aural handicaps the problem is real, and, too often, the only recourse for advancing deafness is in the hearing aid and lip reading. Appropriate lenses for vision and adroitly fitted dentures are universally accepted, but the hearing aid still suggests the stigma of a trade-mark. The paper we have heard proves that fenestration is coming into its own. It is a far cry from the day, but a few years back, when, with a Philadelphia colleague, your speaker stood watching a fenestration operation performed most skillfully and successfully, but which consumed four hours of time under none too pleasant a local anesthesia, to the day last fall when a cheerful patient whose deafened ear Dr. Smith had corrected, and under a short general anesthesia, entered my office fairly radiating optimism.

Returning to a discussion of this paper, three things were most pleasing: (1) the skillful way in which the writer quieted the wrangle of many decades over the actual pathology of otosclerosis by the neat substitution of the term "clinical otosclerosis," (2) his courageous decision that in clinical otosclerosis, even with advancing loss of nerve function, there is a period of grace during which fenestration may still save the hearing, and (3) the fact that his operative time has been shortened and, as I inferred, general anesthesia is used instead of local. This has been a clear-cut, finely prepared paper, and after hearing it we believe the fenestration window will not close. We accept the author's dictum that this work can be done only by a trained and skillful operator.

# FLUORESCENCE WITH THE WOOD FILTER AS AN AID IN DERMATOLOGIC DIAGNOSIS

## Observation on Patients at Bellevue Hospital

MAURICE J. COSTELLO, M.D., and LOUIS V. LUTTENBERGER, M.D., New York City

THE Wood light was invented in 1903 by the American physicist, Robert William Wood. It is a light which has been passed through a filter that absorbs visible rays but allows a portion of the ultraviolet rays to be transmitted. It has fluorescent-exciting properties.—It has been employed in industry to determine the difference in various metals, chemical ingredients, and textiles;<sup>1</sup> in banking houses and similar institutions to detect counterfeit currency; in medicolegal problems;<sup>2</sup> and, more recently, in ophthalmology,<sup>3,4</sup> pathology,<sup>5</sup> mycology,<sup>6</sup> and in dermatologic diagnosis.

It is the aim of this paper to show that the Wood light, although not producing the characteristic distinctive color changes which are observed in some fungous infections of the scalp, is an aid in the diagnosis of nonmycotic dermatoses.

Fine shades of color are not appreciated by many people. The primary colors are recognized by most of us, but a lack of development of the color sense limits the scope of appreciation of many. In order to cope with the various secondary colors seen under the Wood light, we have used as our guide the standard colors as exhibited in Merriam-Webster's *New International Dictionary*.<sup>7</sup>

The color of an object depends on its reaction to rays of light. This accounts for the difference in appearance of certain colors in the daylight as compared with artificial light and the Wood light.

### Types of Wood Lights

The source of radiations in the production of fluorescence is a high-pressure quartz-mercury arc burner sealed within a reflector-type glass bulb. A metal coating of the inner wall of the glass envelope provides strong reflection of the generated radiations. The bulb is operated on a flexible upright from an ordinary alternating current power supply, through a compact transformer. The light used by us was one from the Hanovia Chemical Manufacturing Company of Newark, New Jersey, Serial SC 993—Type 16103 (see Fig. 1). Technical data: power

supply—110–120, 60 cycles, A.C.; wattage—100 + wattage in bulb; operating voltage in bulb—approximately 130 volts; operating amperage—approximately 0.9 ampere.

The bulb has a maximum diameter of five inches, with an over-all length of eight inches. It takes three minutes to reach maximum intensity.

A wide variety of organic and inorganic substances absorb ultraviolet rays of certain wave lengths and convert them into longer wave lengths. This conversion of energy is called fluorescence. Colors and shades of the re-emitted light vary, depending on the chemical composition and purity of a material, many having their own characteristic glow.

For good observation of fluorescent effects it is necessary to eliminate visible light rays, because these tend to diminish fluorescence. A special dark glass filter consisting of sodium-barium silicate plus 9 per cent nickel oxide is mounted on the front of the bulb. This filter is practically opaque to the visible light generated in the bulb, but transmits the bands around 3,660 angstrom units (the most effective wave lengths to cause fluorescence). Goodman worked with a Corning glass special filter, G.986A, which permitted the passage of ultraviolet to 2,400 angstrom units.<sup>8</sup>

Office ultraviolet lamps may be used with a Corning glass violet ultra, No. 586, of a thickness of 4–5 mm. interposed between the ultraviolet source and the object to be examined. It is suspended by and incorporated in a black rubberized focusing cloth to exclude the visible ultraviolet rays. This is a cumbersome, time-consuming method.

A 200-watt Corning glass electric bulb may be used in an ordinary floor lamp for fluorescence. Fungous-infected hairs may be detected with this light, but it is not practical for other examinations. It emits a reddish glow, radiates a great deal of heat, and excites weak fluorescence.

For the best results, examination of patients or materials should be carried out in a dark room. Examination is occasionally enhanced if the examiner wears smoked glasses.

### Effect of Wood Light on Normal Person

The hair appears dull and lusterless, devoid of its sheen. White hair fluoresces brilliantly;

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, May 10, 1944.

From the Department of Dermatology and Syphilology, New York University College of Medicine, and the Department of Dermatology and Syphilology, Third Medical (New York University) Division, Bellevue Hospital, service of Dr. Frank C. Combes.

FIG 1. Inspectolite (Wood light).

the extent of grayness can be readily determined. Blond hair appears to be made up of several shades and an occasional red strand is observed. Single gray hairs are frequently observed in children. The face has a ghastly hue and is often covered with many lentigines not visible to the naked eye and not hidden by cosmetics. In the middle vertical third of the face in patients with a somewhat oily skin are seen numerous closely aggregated, pin-point, pinkish elevations emerging from the follicular orifices. This condition is seen on the nose, on the contiguous portions of the cheeks, surrounding the tip of the chin, on the inner half of the malar prominences, and in the glabella region. An analysis of this material indicates that the pinkish color is due to porphyrin,<sup>9</sup> and possibly is the substance which sensitizes the skin to light, because it is found in areas where the skin is affected by photosensitizing diseases such as lupus erythematosus.

The eyelids are violaceous in color, which is barely visible under ordinary light. The pupil of the eye is aquamarine in the white race and yellowish-green in the Negro. The color is due to the density and fluorescence of the crystalline lens. The sclera is of a slate-colored bluish hue. The conjunctival blood vessels are better delineated. In some Negroes and to a lesser extent in members of the white race, irregularly rectangular, glistening, cream-colored bodies are ob-

served on either side of the cornea. These are probably due to the deposition of fat; this observation offers an explanation for the development of pingueculae and pterygii. The periphery of the cornea is grayish-white and not sharply outlined in the white race; it forms a hyperpigmented border in the Negro.

The lemon-yellow color of the external auditory canals is caused by the dried powdery cerumen lining them.

The lips are purplish blue.

The mucous membranes of the mouth can be better studied, because several shades of red can be seen. There is less blending of color of the various anatomic areas than is seen with the naked eye. The median raphe of the hard palate appears as a slightly elevated grayish-white line. The soft palate is of more dusky red hue than the hard palate, and the line of demarcation between the hard and soft palate is better marginated. There is a halo of even duskier redness surrounding the anterior pillars of the fauces, indicating greater concentration of blood vessels. The normal teeth are pearly white; false teeth are black, blue-black, or corn yellow, and seldom white. Tartar is cinnabar red in color; this is especially evident in carious teeth and in those exposed areas of the teeth where there is retraction of the gums.

The hairs of the axillae are whitish in color, because of saturation with sweat, which is the color of milk. The follicular plugs at the elbows are fluorescent because of the keratin content of the plugs.

The external genitals in both the male and female are dusky purplish-blue, which is strongly contrasted with the less vascular surrounding skin.

There is an increase in color due to the superficial blood vessels in the skin just proximal to the finger- and toenails. Fingernails are pearly white and highly fluorescent, as are the palms and the weight-bearing areas of the soles. Keratin structures give this pearl-white fluorescence. The nonweight-bearing surface of the foot is light blue in color.

The region anterior to circumvallate papillae is a highly fluorescent pinkish lozenge-shaped area of varying size. This is observed in men and women and especially in children. The absence of this triangular-shaped pinkish area is suggestive of a dysvitaminosis.

### Fungous Infections

Lewis has demonstrated that the Wood light is an important, easily applied aid in the diagnosis of tinea capitis, tinea barbae, and tinea corporis. Under this light the infected hairs and diseased patches of the scalp, when caused by the

*Microsporon lanosum* or *Microsporon audouini*, fluoresce brilliantly. The individual infected hairs take on a bright, luminous, pale-green color. In addition to the important diagnostic value of this examination, it provides a means of determining the extent of the scalp infection, it is a check on the progress of the disease or the treatment, and it is one of the best practical means of deciding when cure has been accomplished. It is of great importance in detecting those cases of *tinea capitis* in which there is little or no clinical evidence of disease, although the infection may be extensive. It is an accurate, rapid method for the examination of the scalp of large numbers of school children during an epidemic of ringworm. Infected pet animals, such as the kitten, suspected of being the source of fungous infection, may be examined by this method.

The Wood light may also be used in examining suspected or infected headgear and clothes during and after fungous infection of the scalp, as well as contaminated instruments in barber shops, upholstered furniture in the home, and the backs of seats in the children's sections of moving picture theaters.

It has also been used to advantage in studying the color changes of fungous cultures.

*Pediculosis capitis* and *pediculosis pubis* can be detected much more readily by means of the Wood light. It was discovered accidentally in several patients when its presence was not suspected clinically. Although the nits do not fluoresce brilliantly, they are more distinctly visible. This is probably due to the fact that they are thrown into relief by the dull background of hair.

The lesions of *pityriasis versicolor* fluoresce a dull yellow. The extent of the eruption is easily determined.

Chronic paronychia, especially of the monilial type, is more distinctly seen. It appears as a well-circumscribed, dark, grayish-blue area covered with a fine fluorescent scale.

### Syphilis of the Skin and Mucous Membranes

As pointed out by others and as demonstrated by us on numerous occasions, fading secondary syphilitic eruptions and evolving syphilitic maculopapular eruptions which have not appeared clinically are visible under the Wood light. The importance of this aid is obvious in the dark-field-negative primary stage of syphilis when the report of the Wassermann reaction of the blood has not yet been received and after the clinical disappearance of the secondary syphilitic eruption. Clinically healed moist papules and mucous patches can still be seen as dusky pink-

ish-red lesions with an opalescent sheen. Examination of the oral mucous membranes during the eruptive secondary stage of syphilis revealed, as a rule, more mucous patches than we were accustomed to see clinically. They can be seen on the tongue, fauces, and especially on the posterior pharyngeal wall. They are so numerous in the latter location as to account for the syphilitic angina. Syphilitic papules appear as dusky blue with a grayish tone, surrounded by a halo of apparent devascularization or paleness. Macules are more prominent than papules. Papules can be seen overlying the bifurcation of venules on the nonweight-bearing areas of the feet. Chancres appear larger because of the narrow zone of salmon-colored redness, which is not visible clinically. There is a shiny slate-colored sheen to the erosive area of the chancre. Moist papules on the genitals are dull pink in color.

### Chronic Dermatoses

The lesions of many chronic dermatoses undergoing evolution or involution are distinctly visible, although many of the lesions may not be seen with the naked eye. This is true of lupus erythematosus of the fixed type. In several patients with this disease healed lesions not visible to the naked eye could be seen months later with the Wood light. In a patient with acute lupus erythematosus the lesions which had completely disappeared during a remission of the disease could still be seen clearly as powder-blue discolorations on the previously involved sites.

Similar experiences occurred in numerous dermatoses, including acne, psoriasis, herpes zoster, lupus vulgaris, neurodermatitis, seborrhoeic eczema, acute lymphosarcomatosis, etc. In a young woman with seborrhoeic eczema the former lesions, though not discernible to the naked eye, could be seen several weeks after they had disappeared, with superficial roentgen rays. This observation offers the reason for recurrence of the lesions of many chronic dermatoses *in situ*. Pruritus not accompanied by clinically apparent lesions may display the lesions when examined with the Wood light. Satellite advanced lesions not visible to the naked eye can be seen in lupus vulgaris. Evolving lesions of erythema induratum and the scars left by these lesions are distinctly visible as dark-blue areas.

*Verruca vulgaris* fluoresces a silvery white under the Wood light and may be differentiated from *molluscum contagiosum* by the fact that the latter is not fluorescent except for the speck of keratin surmounting the lesion. The follicular plugging of the fixed type of lupus erythematosus, folliculitis decalvans, lichen planopilaris, and lichen spinulosus associated with vitamin A

deficiency are readily observed is highly fluorescent small white conical elevations.

Variouse eczemas reveal a reddish-purple fluorescence several inches beyond the area of clinical involvement on areas that appear quite normal to the naked eye. Ichthyosis of severe type involving the torso as well as the extremities shows highly fluorescent white silvery quadrilateral scaling of unique appearance. Untreated psoriasis may be differentiated from seborrheic eczema by the bright silvery fluorescence of the scales, which is not present in the latter condition.

### Abnormal Conditions of the Oral Cavity and Mucous Membranes

Lesions of the tongue such as syphilitic glossitis and dysvitaminoses are seen in better contrast. Diagnoses of these conditions have been made on several occasions with the aid of the Wood light which would have been missed on ordinary clinical examination. The bald areas are darker red in color with a brownish fringe, and sharply margined on the dorsum tip, and sides of the tongue.

The same is true of lingua plicata and lingua migrans. They are distinctly visible and often occur together.

Subclinical jaundice is often detectable on the oral mucous membranes and, when jaundice is present in this location, the sclerae are similarly affected.

Lichen planus lesions of the oral mucous membranes do not fluoresce but keratinized areas of leukoplakia fluoresce brilliantly. This finding is an aid in diagnosis.

It has been stated that the disappearance of the orange red, elevated coalescing coating on the tongue is an indication of vitamin B deficiency. The coating is abundant in children, less so in well nourished adults and is absent in those suffering from vitamin deficiency. The fissured perleche-like lesions at the angles of the mouth are dusky red, the erythema extending beyond the area of obvious clinical involvement.

It is not unusual to observe dentifrice and mouth washes on the lips and around the mouth indicating the possibilities of dermatitis venenata of these locations.

### Eyes

The scars of interstitial keratitis are easily seen. Their extent, depth, character, and progress can be observed and the shadows of these scars can be seen reflected on the crystalline lens. Subclinical jaundice, as evidenced by decided xeroderma tint of the conjunctivae and oral mucous membranes, can be ascertained. This was observed in several patients who were under in-

tensive treatment with mapharsen. An elevation of the icteric index confirmed this finding. Argynia, with involvement of the conjunctivae and the mucous membranes following overdosage with silver arspenamine in the treatment of syphilis, causes a dark-slate color in the scleral and deep blue in the oral mucous membranes. The formation of vascular loops and Bietot spots in riboflavin deficiency and the keratoconjunctivitis of rosacea are more readily observed and studied. Punctate purpuric lesions are occasionally seen on the palpebral conjunctivae following severe coughing or vomiting when similar lesions are not seen on the skin.

### Epithelioma, Senile and Seborrheic Keratosis

The extent of involvement of the skin in epithelioma can be more accurately determined under the Wood light. This is of importance in treatment by surgery or roentgen rays in order that the entire diseased area may be excised or treated.

Occasionally satellite lesions of malignant melanoma can be seen. Transillumination is a more effective method of inspection when the lesions are located on areas which lend themselves to this form of examination.

Precancerous lesions on the exposed parts of the body, such as senile and seborrheic keratoses, fluoresce brightly by virtue of the fact that they are usually surmounted by dry, adherent keratin material.

### Cicatrices and Keloids

Operative scars are seen distinctly with the Wood light. They are deep purplish-blue to lilac-colored, depending upon their age, width, and depth. In the person with several incisional scars one can roughly determine the relative age of each cicatrix by the density of the color. Sites of previously burned areas of the skin not visible or barely visible to the unaided eye are sharply delineated as shadow-like, dark, bluish-black areas. These smudge-like areas are often visible despite efforts to cover them with cosmetic make-up preparations. The former sites of keloids which have long since disappeared under radiation therapy are visible as dark patches.

What has been said about the aforementioned cicatrices is also true of scars following ecthyma, acne, papulonecrotic tuberculide, lupus erythematosus, lupus vulgaris, epithelioma, alopecia cicatrizzata, tertiary syphilis, neurotic excoriations, and so forth. The punched-out, old scars of papulonecrotic tuberculide appear luscious, this color deepens to dark violet in recent scars. This observation may be applied in crime detection in revealing the scars, invisible in ordinary

light, which have followed plastic surgery operations to change the identity of a criminal.

Recent trauma to the skin following injections into the buttocks over a period of a week were observed as distinct pinhead-sized reddish-blue spots. The total number of injections given could be accurately determined by the number of puncture marks present in a patient who had been treated every three hours eight times a day with penicillin for syphilis.

### Vitiligo and Nevi

There is bright white fluorescence in vitiliginous patches. They are much better visualized under the Wood light because the surrounding skin is darker, especially the hyperpigmented margin. Small patches of vitiligo not observed in normal light can be easily detected. Patients were told of rectangular patches of vitiligo on the cheeks which they never suspected had been present, until they recalled that these areas were sunburned disproportionately to the rest of the face and that they had difficulty in making cosmetics in these areas blend with the surrounding skin.

Freckles are accentuated and people have many more times the number of lentigines than can be seen with the naked eye.

Nevus anemicus can be differentiated from vitiligo more readily because vitiliginous areas partially lose their fluorescence when rubbed, but in nevus anemicus the lesion itself blanches more in contrast to the surrounding area of erythema.

Common moles are a little darker, with a reddish tone. The blue nevus and the black mole are jet black under the Wood light. The chloasma of pregnancy is quite marked, even when not conspicuous in ordinary light.

The port-wine mark, hemangioma, and senile angioma are dark blue with a reddish tone. Some small port-wine marks on the fingers not visible clinically can be distinctly seen as dark-red well-circumscribed lesions which blanch on pressure.

### Exanthemata

We have used the Wood light in studying the acute infectious diseases, such as measles, chicken pox, and scarlet fever. In measles the eruption may be seen before and after its clinical appearance, but the Koplik's spots are better seen in daylight or ordinary artificial light. The strawberry tongue of scarlet fever is much better appreciated under the Wood light. It is covered by a heavy pinkish-red coating with dark-bluish punctae. The desquamation in scarlet fever is observed earlier, especially when there is separation of the upper layers of the epidermis at the

ends of the fingers. These areas fluoresce and the margins of the loose skin appear quite white.

The mucous membrane lesions of varicella stand out in sharper contrast on the hard and soft palate than they do under natural light, but the Wood light is of no additional aid in examining the cutaneous lesions.

### Stains on the Skin

A number of patients have been observed under the Wood light who showed golden-brown band-like discoloration of the forehead and wrists caused by hat-band and wrist-watch band dyes.

Fluorescent stains of various colors are seen frequently on the body which are caused by substances applied to the skin. Perspiration creams, when applied to the arm pits, give a lemon-tinted fluorescence. Recently applied lotions, salves, and powder fluoresce. Oftentimes traces of these materials may remain even after thorough bathing with soap and water. Dermatitis venenata may be caused in this manner.

A patient who complained of pruritus ani showed a yellow fluorescence in the perianal, buttock, and thigh regions under the Wood light. On questioning, she stated that she had used derma-medicone for the relief of pruritus. This fluorescence persisted in spite of thorough bathing.

Petrolatum (vaseline), when used alone or as a vehicle, is highly fluorescent and must be removed before an eruption can be studied under the Wood light. Salicylic acid is fluorescent under certain Wood lights but not with others. The fluorescence of salicylic acid can be masked by interposing a piece of ordinary glass between the filter and the salicylic acid crystals.

### Roentgen Ray Effects

Roentgen ray hyperpigmentation after a single dose of 75 r of roentgen rays, although not visible to the naked eye, can be seen distinctly. An epilating dose of roentgen rays shows a subclinical erythema appreciated only under the Wood light. More information can be gleaned from this form of inspection of radiodermatitis. The telangiectases are more distinct; interspersed areas of hyperpigmentation, atrophic areas of depigmentation, and fluorescent precancerous keratoses are better visualized. The area of involvement extends beyond that which is visible to the naked eye.

### Skin Tests

The reaction of erythema in the skin following skin testing with tuberculin, trichophyton, oidy-mycin, etc., may be seen for a considerable period of time after every vestige of erythema has disappeared clinically. An area of light blue

color, oval in shape and measuring 6 by  $3\frac{1}{2}$  inches, could be detected under the Wood light a month after an intradermal test with oidiomycin had been performed, even though no trace could be seen clinically. Delayed subclinical reactions with patch tests were also observed.

### Summary and Conclusions

1. Several types of Wood filters with varying degrees of fluorescence are described. The Wood filter employed by us transmitted the bands around 3,660 angstrom units. Fluorescent effects observed with one Wood light may not be seen with another of different angstrom unit transmission.
2. The appearance of the skin and mucous membranes of the normal person under the Wood light is described.
3. The most important application of the Wood light in dermatologic diagnosis is in detection of fungous infection of the scalp. It is particularly valuable in the rapid examination of the scalp of large numbers of school children. Fluorescent fungous-infected patches and hairs can be visualized with the Wood light, often when there is no clinical evidence of tinea capitis.
4. Evolving and fading syphilitic maculopapular eruptions are visible under the Wood light.
5. The true extent of the eruption of many chronic dermatoses may be better discerned.
6. Cutaneous and mucous membrane lesions which do not show definite color contrast with their background, as a rule, can be more distinctly seen under the Wood light.
7. The Wood light is of considerable aid in detecting the materials which commonly cause dermatitis venenata. This observation may be applied in the study of industrial dermatoses.
8. The Wood light is an aid in dermatologic diagnosis.

### Discussion

Dr. Herman Goodman. The rare accomplishment of the systematic observation of production of the new method of utilization in the ultraviolet light utilized, is dependent on the source of monochromatic light. The clinical study is evidence of the difference between fluorescence and reflection of ultraviolet light. The exciting radiation is repeated each time it is repeated. Two observations of color of fluorescence at recording the skin have failed energy involved.

The offices of practitioners are the ultraviolet source of nickel glass, or emitting passageway easily fitted.

In a dark of vibrations of visual sensation of tissue of the dermatologic Nothing The gorgeous because of pearly yellow of one and the same source of bluish neck to the most severe types of flatly reiterated in current under types, referred to by "cervix", the presence or may be determined by the of tincture of iodine, which of squamous epithelium but of area covered by columnar is present, the identification of organism by means of hanging drop in saline should elimination. infection is longer cervicitis. It among unmarried are well known. its cardinal mani- described, but they of one and the same topic and microscopic to the most severe types of flatly reiterated in current under types, referred to by "cervix", the presence or may be determined by the of tincture of iodine, which of squamous epithelium but of area covered by columnar is present, the identification of organism by means of hanging drop in saline should elimination. Syphilis and other factors of cervicitis are not be forgotten in all

advanced cervicitis may simulate they fall of grooves and

tants, dyes, etc., or industrial dermatosis, is uncovered. The evidence produced under fluorescence is valuable in detecting the cause of otherwise unrecognized reactions to insult of the skin, such as the application of hair dye, eye wash, skin cosmetic, fur dye, etc. Details of results of examinations have been published, as noted in the list of references attached to the paper of Costello and Luttenberger.

The most exciting experience in the study of the skin with fluorescence under filters permitting passage of radiation less than 3,000 angstrom units is the vivid appearance of salicylic acid. The interposition of a piece of ordinary glass casts a shadow obliterating the specific fluorescence of the salicylic acid. The experience recited by Drs. Costello and Luttenberger with the prototype of the Wood filter, effective filtered radiation of about 3,660 angstrom units, augments rather than duplicates the published observations made with Corning glass G-986-A filter and mercury vapor arc in quartz source of ultraviolet.

The need for secret signalling by our armed forces has intensified investigation of sources of black light and fluorescent and phosphorescent materials. Ships are kept in line and at proper distances from each other under certain conditions of night maneuvers through invisible ultraviolet sources of radiation

impinging upon reacting lenses of the observer. In a recent address, E. W. Boggs, of the Westinghouse Electric Manufacturing Company, Bloomfield, N.J., revealed details of activating light sources for luminescent materials. A special glass bulb impregnated with coloring material, enclosing a 250-watt incandescent photoflood lamp, permits spectral radiation in the near ultraviolet zone, 3,000-4,600 angstrom units. This lamp operates at exceedingly high temperature. Activated intermittently by electric current, the average approximate anticipated useful life of this bulb is fifty hours. A recent but limited experience with a commercially available incandescent bulb designated by the Westinghouse Company as purple X-250-watt A-21 in red-purple finish indicates it is a valuable addition to the diagnostic armamentarium in dermatology of the physician. The bulb does not replace the mercury vapor arc in a quartz source of radiation with an effective filter Corning G-986-A. The incandescent red-purple photoflood lamp and the mercury vapor arc with filters equivalent to the Wood nickel filter do not fluoresce the salicylic acid group of drugs. It will be interesting to have systematic studies made with the recently released red-purple photobulb A-21 incandescent source of filter combination.

#### CHINA'S JUNIOR MEDICAL AIDES

Eight thousand young Chinese men and women—many of them only 17 years of age and none over 25—are carrying the burden of medical treatment of wounded Chinese soldiers. The young medicos are known as junior medical aides, and go into the field after intensive training of six and even three months.

These facts were told by Lt. Gen. Robert Khosheng Lim, chief of the Supervising and Planning Commission of the Chinese Army Medical Service, who has just arrived in this country on a military mission.

China's critical shortage of trained medical personnel, described by General Lim as "the Chinese Army's most serious medical problem," is responsible for the emergency training of the young medical aides. In Free China today there are only about 6,000 fully trained M.D.'s, he said. Only 3,000 of these are serving with the Chinese Army.

The training of China's young army of medical aides is accomplished in six Emergency Medical Service Training Schools, which were organized partly with funds supplied by the American Bureau for Medical Aid to China, and which are today being supported by funds obtained by United China Relief through the National War Fund.

Only the most basic medical training and instruction in only the most common diseases can be given to the junior medical aides, since the need for their services is so great, Dr. Lim said. But the efficacy of their training and the young people's efficiency in putting into practice their limited medical knowledge is shown partly in the fact that there has been no major epidemic in the Chinese Army or in China for six years.

"Further proof of the worth of the Emergency

Medical Service Training Schools," said General Lim, "is the fact that fatalities among Chinese wounded, which were as high as 50 per cent in 1937 and 1938, are now only about 5 per cent."

The training given to the medical aides consists of instruction in first aid, in setting bones and treating fractures, in immunization, in preventive medicine, and in general sanitation.

The Emergency Medical Service Training Schools graduates go into small towns or villages near the front lines and set up medical stations and dispensaries.

"Civilians and soldiers alike are given medical treatment," said General Lim, "because in areas where the Chinese soldiers depend for food and other necessities upon the local population, and especially when they remain over long periods in one area, the good health of the civilians is essential. Many backward villages which never before had medical service of any kind are now receiving it."

Shortage of equipment must often be handled with new methods, such as those used in vaccinations. In normal medical practice, an individual ampule of vaccine is used for each person. But because it is impossible to obtain materials for large quantities of ampules, the Chinese Army Medical Service is using large ampules containing sufficient vaccine for 100 vaccinations, and is administering to groups of 100 at a time.

General Lim organized the Chinese Red Cross Medical Relief Corps in 1937, and created hundreds of mobile operating units, known as "hospitals on muleback," which for seven years have operated as near as a half mile to the fighting lines. Last June General Lim was awarded the Legion of Merit by President Roosevelt—*Connecticut State M. J.*

# AN EVALUATION OF THE VARIOUS METHODS OF TREATMENT OF CHRONIC CERVICITIS

MORTIMER N. HYAMS, M.D., F.A.C.S., New York City

SINCE Stroganoff<sup>1</sup> in 1893 and Winter<sup>2</sup> in 1896 first called attention to cervicitis as a distinct clinical entity, a vast literature on this subject has accumulated. The causes, effects, and complicating factors have been thoroughly discussed and many methods have been advocated and practiced for its prophylaxis, relief, and cure. Nevertheless, the relative frequency of this condition has shown little apparent decrease in the last decade. Its widespread prevalence has created an appreciation of the seriousness of cervicitis and has stimulated a greater effort to render more appropriate and satisfactory treatment. It is difficult to say whether this high incidence is due to the failure of curative measures or whether a more thorough examination of patients<sup>3</sup> has detected a greater number of cases.

The cervix has long been recognized as a potential source of infection and as an important factor in pathology. Laboratory investigation of the pathologic reaction of the cervix to infection, supplemented by more intense clinical study, confirmed the fact that cervicitis is not a surface infection but involves the entire structure, including the glands and lymphatics. Eradication of the infected tissue, together with its contained glands, is essential, not only as a therapeutic measure but also to preclude the possible subsequent development of cervical carcinoma.

Its anatomic location and physiologic function render the cervix especially susceptible to trauma and infection. An understanding of the anatomic distribution of the lymph channels and nodes which drain the cervix and uterine body is necessary for the proper interpretation of cervical infection. This has been elaborately described by Sellers.<sup>4</sup> The lymphatic inter-relationship of the cervix and urinary bladder has been emphasized. Herrold<sup>5</sup> *et al* state that disturbance of the lower urinary tract has been completely relieved by coagulation of the chronically infected cervix. Winsbury-White<sup>6</sup> in 1933, in experiments on animals, showed the spread and ascent of infection from the cervix to the ureter and kidney.

The intimate relationship of the cervix to contiguous structures has been likewise cited as a

cause of infection and reinfection of the pelvic organs, vagina, and urinary tract. Graffagnino<sup>7</sup> contends that the infected cervix is a causative factor in systemic infection, ranking in occurrence and consequence next only to the teeth and tonsils. Kostmayer<sup>8</sup> cites specific instances of arthritic and other types of invasion which were cured by local treatment of the infected cervix. Davis<sup>14</sup> states that in his experience, when streptococci can be grown from the cervix of a patient with arthritis, cleaning up the cervical infection usually is followed by clinical improvement of the arthritis, and in a few cases in which other foci had been previously removed the degree of relief was beyond expectation.

Trauma from childbirth or instrumentation does not of itself result in cervicitis. The invasion of one or more pyogenic organisms such as the Streptococcus, Staphylococcus, colon bacillus, Pneumococcus, or similar bacteria is essential. If a laceration does not heal spontaneously in eight weeks it is evident that infection is present. Gonococcal infection is no longer considered the most frequent cause of cervicitis. It is not uncommon, however, in young unmarried women (Maloney<sup>9</sup> and Baker<sup>9</sup>).

The symptoms of cervicitis are well known. Leukorrhea is still regarded as its cardinal manifestation.

Many types of cervicitis are described, but they are essentially only parts of one and the same process. The macroscopic and microscopic changes from the simple to the most severe types are clearly and adequately reiterated in current literature. In the milder types, referred to by some as the "innocent" cervix, the presence or absence of erosions may be determined by the surface application of tincture of iodine, which stains the stratified squamous epithelium but does not affect the eroded area covered by columnar cells. If infection is present, the identification of the offending organism by means of smears, cultures, or hanging drop in saline should be part of every examination. Syphilis and tuberculosis as causative factors of cervicitis are rare, but they should not be forgotten in all suspected cases.

Some types of advanced cervicitis may simulate carcinoma. They fall into three groups: benign, precancerous, and malignant, and their differentiation is of the utmost importance. A biopsy should be taken if the changes in the cervix suggest the possibility of any of these con-

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, May 5, 1943.

From the Department of Gynecology, New York Post-Graduate Medical School and Hospital, Columbia University.

ditions. Sections of the tissue should be taken from several areas of the cervix and subjected to a thorough microscopic examination by a competent pathologist. These specimens are best removed by a high-frequency cutting current to prevent the dissemination of cancer cells.

Both pathologists and gynecologists are convinced that some of the tissue changes of chronic cervicitis are undeniably precancerous (Bulard<sup>10</sup>).

Bailey<sup>11</sup> states that the ultimate sequel to erosion is malignancy, and Ewing<sup>12</sup> believes that cancer arises only on tissue which has become altered by chronic irritation. Wolfson<sup>13</sup> found that 3.95 per cent of all women who reach the age of 35 develop carcinoma of the cervix.

Davis<sup>14</sup> believes that there may be individual and sectional differences of opinion regarding various corrective forms of treatment, but most will agree that all cervical lesions should be kept under observation and treated by some method until satisfactory healing has been brought about.

Matthews<sup>15</sup> classification of various phases of cervicitis is of distinct aid to the clinician in the selection of treatment:

Group 1. The recently lacerated cervix of four to twelve weeks' duration, with a superficial infection; the nulliparous cervix, the seat of a mild gonorrheal or nonspecific infection.

Group 2. The lacerated, eroded cervix of three to twelve months' duration, with somewhat more extensive and deeper infection than that in Group 1, possibly with a few superficial cysts. This may be found in a moderately infected nulliparous cervix.

Group 3. The lacerated, everted, eroded cervix of two to five or more years' duration, moderately infected and with or without visible cysts. This is found in the moderately deeply infected nulliparous cervix with or without erosion and cyst formation.

Group 4. The old, lacerated, everted, eroded, hypertrophied, cystic cervix deeply and extensively infected and of long duration (from ten to forty or more years). The same condition is found in the extensively infected, cystic, hypertrophied nulliparous cervix.

The value of prophylactic care is mentioned by many to eradicate the early types of cervicitis and to prevent its progress. This may best be accomplished by meticulous asepsis and gentleness in all manipulations of the cervix, routine postpartum examination, and early treatment of all postpartal infections. Primary trachelorrhaphy, the immediate or intermediate repair of any cervical laceration over 15 cm. following childbirth, is now a recognized procedure, but it should be done only by the competent obstetrician who has been trained in the art of vaginal

plastic surgery (De Lee,<sup>16</sup> Goff,<sup>17</sup> Danforth,<sup>18</sup> Bloss<sup>19</sup>).

It is evident that the majority feel that the early eradication of the diseased glandular tissue, either by destruction or excision, is essential, and for this purpose topical applications are of little or no value. However, Klawns<sup>20</sup> advocates the vaginal and cervical application of insulin for cervicitis in both the diabetic and nondiabetic patient. Platz<sup>21</sup> has had good results with the Fissan silver powder. The intracervical application of solutions such as Filho's caustic has been extensively used by Marcel<sup>22</sup> in papillary and granular erosions, but he prefers coagulation. Guillemin<sup>23</sup> finds this solution superior to coagulation; few infections of the adnexa follow its use, but subsequent dilatation is necessary. Hamant and Rothan<sup>24</sup> find that atresia usually follows its application.

It is apparent from the recent publications that the removal of the diseased cervical tissue can be accomplished by simpler and less drastic measures than by major operative intervention. In the past years, there has been a growing tendency to utilize electrotherapeutic measures for this purpose, the most popular of which are cauterization, coagulation, and conization.

### Cauterization

The nasal tip and heavy-duty cautery destroy the diseased tissue by direct contact and the dissemination of heat. The amount of destruction depends on the size of the cautery tip and the duration of its application. Of the two, the nasal tip is the one more frequently used, for it requires no hospitalization or anesthesia. Superficial stripes, no more than one-eighth of an inch in depth, are placed on one or both lips, leaving islands of mucous membrane between. Danforth advises that one should not cauterize too high or too deep in the cervical canal, and that the stripes must not be placed too close to each other. If it is necessary to recauterize, a considerable length of time should elapse between treatments—months, not weeks. Costello<sup>25</sup> feels that this is the method of choice in the treatment of cervicitis during the childbearing period. It is used by Sichel<sup>26</sup> for extropions and erosions of the external os and by Gann<sup>27</sup> for simple papilloma and follicular erosions. Davis Dannreuther<sup>28</sup> and others utilize this modality for minor lacerations, erosions, and eversions, Soter<sup>29</sup> for superficial and recent lesions, and Roblee<sup>30</sup> for postpartum erosions and infections. Hunner,<sup>31</sup> Ground,<sup>32</sup> Ofut,<sup>33</sup> Ludden,<sup>34</sup> and others state that cauterization gives satisfactory results in the majority of cases. Maloney and Dallas<sup>35</sup> use it exclusively and report that infection never occurs, and that hemorrhage and stenosis are rare.

The dangers of the nasal tip cautery are emphasized by Hamant and Rothan Roblee states that it burns the superficial parts before penetrating the deeper tissues. Baker finds that stripping the cervical canal does not destroy the deep, infected cervical glands. Frost<sup>36</sup> notes carbonization of the tissues with resulting scar formation and that this procedure is not without danger because of latent hemorrhage. Secondary stenosis and painful menstruation have been observed by Stark.<sup>37</sup> Kimble<sup>38</sup> states that relapses or reinfections occur if all the glands are not destroyed and that cauterization either fails to cure or, if it does cure, produces atresia of the cervical canal. He condemns its use during the childbearing age and considers it obsolete. However, in reviewing the end results of 611 cases, Tompkins<sup>39</sup> concludes that cauterization gave the same percentage of cures and relief from leukorrhea as trachelorrhaphy, the Sturmdorf operation, or amputation of the cervix. In our opinion, the nasal tip cautery has a definite place in the treatment of minor lacerations and erosions.

As the term implies, the heavy-duty cautery is considerably larger than the nasal tip, and hospitalization and anesthesia are required for its use. The Post cautery so widely advocated a decade ago is not mentioned in current literature. Where the cervical canal is not sufficiently large to permit free manipulation of the terminal dilatation is essential. With this instrument the entire surface of the canal, as well as that of the erosions or ectropions, is thoroughly cauterized. Stearns<sup>40</sup> advocates deep intracervical cauterization if a superficial application does not cure a persistent and excessive discharge. It is recommended by Soter for extensive pathology or in very chronic or obstinate gonorrheal cases. Young finds it cures 50 to 60 per cent of cases of leukorrhea. Baker notes that atresia frequently follows the use of the heavy-duty cautery. Cannell and Douglass<sup>41</sup> point out that complications may follow cauterization with either the nasal tip or the heavy-duty cautery, and that the occurrence of subsequent widespread pelvic infections is evidently more frequent than is supposed.

### Coagulation

Another method for the destruction of the diseased endocervix is by electrocoagulation accomplished by the application of heat with a high frequency current through an active electrode placed in contact with the cervix or cervical canal. Arenas and Emanuel<sup>42</sup> found that the different effects obtained depended on the intensity of the current, duration of its passage and the form of electrodes that were used. Roblee states that the deeper tissues are affected before the

superficial. As a result of studies of coagulation of the uterus of rabbits, Moghano<sup>43</sup> concluded that the extent of healing depended on the size of the electrodes, the distance between them, the amount of current, and on the amount of water in the tissues. Very little scar formation follows its use, according to him.

Two types of high-frequency current are in use, bipolar (d'Arsonval) or unipolar (Oudin). Many use instruments of their own devising. (Unde,<sup>44</sup> Cherry,<sup>45</sup> Ground, Kimble, Remington,<sup>46</sup> Marcel, Soter, and others.) The application varies, some use an inactive plate on an external surface of the body, the active electrode in contact with the cervix or in the cervical canal. The Cherry instrument incorporates both poles in the one electrode. The amount of current used by different operators ranges from 200 to 2,200 milliamperes. There is also a difference of opinion as to the duration of treatment—a few seconds to fifteen minutes—and the site and method of application of the active electrode. The majority maintain that the active electrode should be held in one position during the treatment, but Kassebohm and Schreiber<sup>47</sup> and Kimble advocate rotating the instrument during procedure in order to preclude too great an amount of coagulation at one site. These extreme variations are due to the different types of high frequency apparatus used and the failure of manufacturers to standardize this type of equipment.

There are numerous references to the efficacy and results of coagulation. Many prefer this modality to the exclusion of others. Frost states that there are few cases of cervicitis or eroded cervixes which will not respond to coagulation if it is properly used. Kimble reports complete recovery in 80 per cent in a series of cases in six to eight weeks, following one application. Even in severe cases he obtained good results. The rapid and permanent cure without interference with subsequent pregnancy and delivery is reported by Arenas and Emanuel. Risacher<sup>48</sup> finds no contraindications for coagulation except tuberculosis. In 150 cases treated by this method, he had satisfactory results in 132, and in this series he had 24 cases of gonorrhea and 29 postpartum patients. Roblee goes so far as to say that coagulation will properly replace the Sturmdorf operation. Sichel, Barrett,<sup>49</sup> Ollervides,<sup>50</sup> Stark, Remington, Hamant, and Rothan are strong advocates of this procedure. Baker uses this modality before proceeding with trachelorrhaphy. Chosson and Casalta<sup>51</sup> found by biopsy that with coagulation the affected tissue was destroyed and replaced by normal tissue.

A few writers mention complicating factors following coagulation. Hiller feels that cauterization and coagulation are not entirely harmless

procedures and reports two deaths due to coagulation. Merletti<sup>52</sup> states that hemorrhages may ensue. As a causative factor in atresia of the cervix, coagulation is cited by Kassebohm and Schreiber. They suggest that in order to overcome the possibility of stenosis, a two-stage procedure be carried out with subsequent dilatation of the cervix with a uterine sound. In 1934 Ground believed that with coagulation the scar tissue was less in amount and density than with cauterization. However, in 1936, he concluded that with both of these procedures, the resulting cicatricial tissue and subsequent stenosis were equally frequent. The writer believes that coagulation has a definite place in the treatment of cervicitis in selected cases, in the hands of a skilled and careful operator.

The Oudin current, a monopolar high-frequency current, is used very little in this country. It destroys the diseased cervical tissue by fulguration or desiccation. The single electrode is applied directly to the tissue to be destroyed. Marcel and Ground found it applicable for surface erosions. Hamant and Rothan conclude that the results are unsatisfactory.

### Copper Ionization

Ionization with copper or zinc, one of the oldest electrical modalities, has recently been revived and is receiving increasing attention. Destruction of the diseased tissue is accomplished by introducing a copper or, rarely, a zinc, electrode attached to the positive pole of a galvanic current; the inactive electrode is attached to the negative pole. Several applications are required. Guillemin finds it effective for some types of cervicitis or erosions, principally the milder forms. Forman<sup>53</sup> believes that it approximates the ideal treatment. Tovey<sup>54</sup> has found it more satisfactory than coagulation. Ground, at present, is of the opinion that copper ionization is indicated in many cases with prevailing local symptoms such as leukorrhea, bleeding, or backache, and concludes that the amount of scar tissue is not so great as with other electrosurgical modalities.

### Conization

Conization (Hyams<sup>55</sup>) was devised to remove the diseased endocervix by means of a special instrument with a fine high-frequency cutting current which produces a minimum of coagulation. The instrument is constructed to conform to the spindle shape of the cervical canal and the cutting element removes one-eighth of an inch of endocervical lining (the thickness of the cervical gland bearing tissue) with each revolution. Crossen<sup>56</sup> has modified the shape of the wire tips so that a larger amount of tissue may be removed by

the terminal portion of the loop. By a microscopic study of the tissue excised by conization, Mason has shown that the cut surface shows a minimum of coagulation and that the specimen is unimpaired and satisfactory for microscopic study.

Graffagnino describes this method as simple and satisfactory, and advises its use in practically all forms of chronic cervicitis. In his report of 400 cases, 95 per cent showed relief of symptoms, anatomic restoration, and preservation of function. Mason<sup>57</sup> stresses its simplicity and economic value and claims that little or no bleeding occurs and that subsequent stenosis is nil. He states that it results in as high a percentage of cures as the Sturmdorf operation, which he believes is the best of the surgical procedures. Adair<sup>58</sup> states that conization has its place. Tracey,<sup>59</sup> Davis, Barrett, and others find it satisfactory in selected cases. Reuth<sup>60</sup> has used it since 1928 with good results. He eradicates the diseased cervical tissue by conization and treats a complicating pelvic cellulitis by medical diathermy. Its value has also been emphasized by Kostmayer, Dearman,<sup>61</sup> Stadiem,<sup>62</sup> Dannreuther, Sellers, Davis, and others.

Contrary to the opinion of others, Ground feels that hospitalization and anesthesia are required for conization. Kimble, in 1935, believed that the radio-knife and conization destroyed too much tissue and thought that with improved electrodes this objection could be overcome. With his recent instrument, a terminal loop, he now resects longitudinal strips from the cervical canal. Stearns, who recently adopted this modality, has noticed stenosis following its use. Bullard contends that wherever a wound is left open to granulate, connective tissue (scar tissue) of varying thickness is laid down. He feels that this should be expected in conization and electrocoagulation. In Boland's<sup>63</sup> experience with coagulation and conization, he finds the latter superior. The objections of several years ago, because of the high cost of the requisite equipment for conization, are not valid at the present time when small inexpensive cutting and coagulation units are available.

### Major Surgical Procedures

The major surgical procedures for the treatment of cervicitis have, to a certain degree, been supplanted by electrophysical measures in the past few years. In order of simplicity of technique, these operative measures may be listed as trachelorrhaphy, low cervical amputation, Sturmdorf-tracheloplasty, Schroder repair, high cervical amputation, and total hysterectomy. These are recognized classical operations which need no detailed description; all require hospitalization and anesthesia.

Sovak and Bullard prefer surgical measures to the exclusion of all others. Primary trachelorrhaphy, the only advance in surgery in recent years, has already been mentioned. There is a difference of opinion as to whether the repair should be made immediately following delivery or within a week (Hunner, Dickinson,<sup>64</sup> Tracey, Bubis,<sup>65</sup> Ryan,<sup>66</sup> and others). Many use both minor and major surgical procedures, and select the type of treatment based on specific indications, most appropriate for the type of pathology present (Davis, Kostmayer, Offut, Dannreuther, Adair, and others).

Of the operative procedures, the Sturmdorf tracheloplasty is the most frequently used in chronic cervicitis (Hunner, Roblee). Mason and Bullard state that it is the best of the operative procedures. Uhma,<sup>67</sup> Matthews, and others have modified the original technic. In recent years very little comment has been made on the Schröder repair of the diseased cervix.

Young<sup>68</sup> believes that amputation of the cervix, even panhysterectomy, is indicated in a number of cases. Bullard, in a review of 261 cases of cervical leukorrhea, states that for its cure, high amputation is perfect, the Sturmdorf excellent, low amputation good, and trachelorrhaphy disappointing. Costello postpones surgery until after the menopause.

### Summary

According to Fulkerson,<sup>69</sup> 85 per cent of all women suffer from some degree of cervical infection. For its relief and cure over sixty different methods of treatment have been advocated, recommended, and practiced, ranging from simple topical applications to the most drastic operative procedures, necessitating hospitalization and anesthesia. The best known and most frequently used by these have been reviewed in this presentation. Only in some instances have the authors made any reference to the type or degree of cervical involvement, the age of the patient, or the presence of any complications.

Why should there be such a diversity of opinion regarding the treatment of this condition? Each method of procedure has many exponents, with a like number condemning its use. The situation is unique in the bibliography of gynecologic therapy, indicating the existence of confusion in the treatment of chronic cervicitis.

Confronted with this formidable list of therapeutic modalities, the selection of the best method of treatment is at times difficult for the experienced operator and even more confusing to the inexperienced practitioner. Ground has aptly said: "No one line of treatment or procedure is effective in curing all forms of endocervicitis.

No set of instruments, however complicated, can hope to meet all the requirements in more than a small proportion of cases."

Successful therapy must be concerned primarily with the patient who has the disease, rather than the disease that the patient has. In the selection of a therapeutic agent for the treatment of chronic cervicitis, it is essential that patient and anticipated therapy be "harmonized." I use the word "harmonized" as best conveying the idea in mind. Webster defines it as "adjusted." Specifically, what we mean by "harmonizing" is determining the type of treatment in accordance with certain factors present in the individual patient. These are: (1) age of patient; (2) degree of cervical involvement; (3) complicating factors; and (4) previous treatment of the cervix.

Is the patient in the childbearing or postchildbearing period? The age is a deciding factor in determining the type of therapy to be used. A very severe cervical infection (Group 4) in a woman past the menopause would necessitate more drastic treatment than one very much younger with a mild involvement (Group 1).

Matthews' classification is based upon the degree of cervical pathology present and ranges from the mildest form in Group 1 to the most severe in Group 4. Necessarily, the degree of cervical involvement must be our guide in deciding the method of treatment to be used after due consideration has been given to the age of the patient.

Other pelvic pathology and serious systemic diseases must be diagnosed and excluded, wherever possible, before any cervical treatment is attempted. The selection of the type of therapy to be used must then be determined, keeping in mind the age of the patient and the degree of cervical infection.

The effect of any previous cervical treatment is important and must be given due consideration when further therapy is necessary.

Many of the numerous methods suggested for the treatment of chronic cervicitis have definite potentialities if used according to the plan of harmonization. The progressive advances in electrotherapeutic measures have practically outmoded major surgery, for each of the former in skilled hands is relatively simple and has proved adequate in selected cases. However, they are dangerous unless the technic is thoroughly mastered. Far too frequently, the unhappy results encountered by some operators are not due to the method of treatment but to lack of mechanical skill and errors in technical judgment.

No one procedure now in use fulfills all requirements for the cure of chronic cervicitis. The age of the patient, the degree of pathology present in

the cervix, the presence or absence of complicating factors and previous treatment of the cervix should be our index to the selection of the method of treatment. One should be familiar with all, and with an open mind utilize that procedure which best fulfills the requirements of the particular patient.

## Discussion

**Dr. Milton E. Kahn, Buffalo**—I want to thank the speaker personally for a very informative presentation.

Disease of the cervix is present in a large percentage of patients who present themselves for medical examination. I should like, at this point, to emphasize the fact that it is our duty as physicians to look for it and to treat it.

Careful cervix check-up should be an essential part of a general physical examination. Its exposure by speculum should be a part of every pelvic investigation and still we are all occasionally guilty of its omission. The postpartum cervix should be carefully followed for at least a three months' period and should be normal on discharge of the patient.

I agree with the speaker that the method of treating the cervix should be individualized for the particular patient. The nasal-tipped cautery electrode persistently used will cure many erosions, eversion, and nabothian cystic formations. This is exclusively an office procedure to be done without anesthesia.

The cautery tip should not be heated beyond a cherry-red. Stripings of the cervix are made as described by our speaker. Slightly deeper cauterization at the external os end of the stripings will, with healing, cause the cervical lips to turn in—a desirable end result. A second or third application may be necessary at intervals of three to six weeks.

The conization technic requires local anesthesia and may be an office or hospital procedure. It is indicated in the more extensive cervical disease, with wide eversion, erosion, and cyst formation. Carefully performed, its complications are few. Occasionally, however, hemorrhage or stricture may result. The first can be largely avoided, as the speaker has said, by a thorough knowledge of the intensity of the current used.

As to the second, the passage of cervical dilators, one, two, and three months later, will almost certainly avoid any troublesome stricture. Some of us have coned the cervix, even though it appears essentially normal, as a routine preliminary to supracervical hysterectomy. This removes the junction of the columnar epithelium of the cervical

canal with the squamous epithelium of the portio, an area where carcinoma may take its inception.

Finally, may I emphasize the need for biopsy and pathologic examination of all suspicious cervix tissue. Such routine handling of all conization specimens may occasionally uncover an otherwise unrecognized malignant lesion.

## SPANISH MEDICINE

The Prime Minister's recent references to Spain provide an occasion for reflection on the history and present condition of medicine in that country. Almost exactly one hundred years ago an English traveller of exceptional discernment described, among other characteristics of the contemporary Spanish scene, the low standard of medical education and practice, the menial position of the medical profession, and the hostility of Church and aristocracy to progress. He asked "Can it still be wondered that their textbooks and authorities should too often be still Galen, Celsus, Hippocrates, and Boerhaave?" adding that "the names of Hunter, Harvey, and Asley Cooper are scarcely more known among their M.D.'s than the last discoveries of Herschel." That Spanish medicine should have lagged so far behind is remarkable when one considers the important part played until the thirteenth century by Spain, and especially by the School of Translation at Toledo, in the rediscovery of Graeco-Roman, and the transmission of Arabic medicine. In succeeding centuries the darkness is hardly relieved except by Miguel Servet (Servetus), who, bold enough to question Galen but not bold enough to face the ecclesiastical music, fled from Catholic Spain to Calvinistic Geneva, only to perish a victim of fanaticism equally ruthless in its opposition to truth and light.

There are evidently some in Spain who feel that their country does not receive a just recognition in foreign medical histories. Thus, the translator of the Spanish edition of the standard English-language work found it necessary to add a 103-page appendix on the history of Spanish medicine. Similarly, a Spanish edition of a popular English history of surgery is amplified by a 51-page appendix on "Surgery in Spain." It must be confessed that a reading of these appendices does little to encourage the view that important Spanish contributions have been overlooked. Yet in the Arts and those other fields of human endeavor by which a nation's progress is measured Spain occupies a sure and important place, and those Spanish medical men who have in recent years found the opportunity to work in clinics and laboratories in Britain and the Americas have shown no lack of scientific talent and aptitude. The reason for this poverty of medical science in a nation whose natural genius cannot be doubted must surely be sought in the anachronistic survival of that spirit of authoritarianism which is the mortal enemy of experiment and discovery.

In a search for significant Spanish contributions to the body of medical science it is necessary to turn to one who died only ten years ago in Madrid—Santiago Ramón y Cajal. Even Cajal lamented

that Spain owed almost all it had of science and technology to other countries. In a paper read recently in Spanish at the newly founded Instituto Español in London convincing reasons were given for regarding Cajal as the most illustrious Spaniard of the last century. Without belittling the importance of the arts, of philosophy, and of religion, it is not by these paths, but through science, that Spain must find her salvation in the twentieth century. The layman may find it difficult to appreciate the greatness of Cajal's work, which was in the domain of fundamental biological science and did not result in those practical applications which attract popular interest and acclaim, but apart from the direct value of his work, it would be difficult to overestimate the indirect influence of Cajal on Spanish thought. He opened the eyes of many Spaniards, who, then and since, first saw beyond authoritarian barriers the more spacious world of scientific inquiry, criticism, and objectivity, and to them his memory remains an inspiration which forms a link between those in exile and those at home. For the first time medical scientists of other countries found it necessary to learn Spanish in order to follow new discoveries in the original. The many honors which were showered upon Cajal from abroad at a time when the national prestige of Spain was at its lowest ebb had an important effect on the public and official attitude to science. It is interesting to speculate upon what would have been Cajal's view of the position of Spain in the present world-wide conflict. Perhaps the answer may be found in his own words: "In the democratic State all liberties are sacred except one—the negation of liberty. And all rights are legitimate except this—the mental deformation of future citizens. We respect as sacrosanct the precious germs of reason, for they belong not to us but to God."

There is evidence that the values for which Cajal stood have not been entirely extinguished in the Spain of today, and recent British visitors have spoken with particular enthusiasm of the research on nutritional deficiencies which is being undertaken in the institute at Madrid directed by Prof. C. Jiménez Díaz. Spanish has not hitherto been regarded as a medically or scientifically important language, but in Argentina, Mexico, Chile, and elsewhere in the Spanish-speaking world active centers of medical investigation exist or are developing, and it seems not unreasonable to suppose that Spanish will in the future achieve an important position not only as the language of saints and soldiers, of poets and philosophers, but also as a medium for the communication of discoveries in medicine and other scientific fields.—*British M J June 17, 1944*

# GOALS AND OBJECTIVES IN PSYCHOTHERAPY

LEWIS R. WOLBERG, M.D., Kings Park, New York

THERE are some neurotic patients so keenly intent on getting well that they progress almost spontaneously to cure in an atmosphere of helpfulness and understanding such as is provided in the physician-patient relationship. The majority of patients, however, left to their own resources, stumble into emotional blind alleys from which they cannot extricate themselves without considerable help from the physician. To a large extent this help involves active direction toward mental health goals and objectives. Experience has shown that where psychotherapeutic aims fall short of adequate goals a relapse of illness is almost inevitable.

What criteria can we use to evaluate the adequacy of our objectives? Is freedom from symptoms a sign that the patient has returned to health, or are more subtle changes in personality to be desired? Should treatment cease when we have acquainted the patient with his character assets and liabilities and have shown him how to pattern his life around them? Is the goal of normality a permanent alteration in the character structure, and must this alteration be in harmony with the character of the average person in the culture? How much are we to stress a liberation of the self from the shackles of repressive mores, and how wise is it to encourage the expression of biologic promptings at variance with the cultural norm?

There are some schools of psychotherapy whose sole objective is the removal of symptoms. Anxiety, conversion manifestations, phobias, obsessions, compulsions, depression, and psychosomatic phenomena are looked upon as isolated entities that impair the functional efficiency of the psyche like a diseased gall bladder upsets the entire digestive system. Suggestion, persuasion, thought control, progressive relaxation, purposeful forgetting, and the plunging of the self into extroverted activities are aimed at the symptom as if it were a foreign body whose presence obstructs an otherwise intact psychic mechanism.

No issue is taken with the occasional successes scored by this type of therapy. Successes do occur and there are certain personalities who are able to forestall complete emotional collapse by practicing such devices as "riding their symptoms," substituting innocuous for painful thoughts, frenzied pursuit of social activities, and a punctilious observance of ritual and prayer.

In justification of this therapy it must be said that many persons refuse to accept more intensive treatment or are so intellectually or financially handicapped that a more exhaustive analysis of their problems is beyond their means. In these cases the mastery of symptoms helps the individual gain freedom from excruciating distress and, in some instances, permits him to attain to a more useful existence.

Nevertheless, one must not minimize the superficiality of this approach, for the dynamic sources of tension and anxiety go untreated. It is as if in foot pain resulting from a hobnail we were to concentrate on the mastery or the deadening of pain and totally neglect the repair of the shoe.

To illustrate this more concretely we might consider the case of a man who sought treatment for heart palpitations, difficulties in breathing, and various phobias which incapacitated him so that he had to give up gainful employment. His childhood had been spent under the tyrannical pressure of a neurotic, domineering mother whose own need for mastery and power impelled her to bring her son completely under her control. Blind compliance and submission were rewarded with indulgences, while any display of rebelliousness or desires for independence brought threats of abandonment and punishment. Self-strivings, such as assertiveness, investigative curiosity, and self-fulfillment, were stifled as they emerged until the child developed into a crushed creature of his mother's will with a lack of initiative and with convictions that he lived solely by his mother's grant. Powerful hostilities and resentments generated themselves constantly as he was forced to smother his independence and assertiveness. But because any outward display of rage aroused the wrath of his parent, the boy found it mandatory to repress all overt expressions of his indignation.

As he matured his interpersonal relationships patterned themselves around an overvaluation of the capacities and aptitudes of other people, an automatic yielding to their wishes and demands, and a minimization of his own rights and abilities. While he conformed to the letter of what he felt was expected of him, he burned inwardly with resentment which became more and more overwhelming as time went on. Subversively he expressed his resentment in the form of stubbornness and a negative attitude directed against the world at large. His defiance mounted and finally reached a peak in his relationship

From the Department of Psychiatry, the New York Medical College, Flower and Fifth Avenue Hospitals.

with his wife, toward whom he reacted as if she were virtually a reincarnation of his mother. He felt exploited and trapped until he could no longer conceal his resentment from her. Episodic outbursts of aggression were invariably accompanied by anxiety, with heart palpitations, choking sensations, feelings of helplessness, and fears of impending death. Contrition, remorse and various acts of penitence compulsively followed. Nor could feelings that it was wicked and immoral to hate his spouse crush the rage that seethed within himself. He conjured up fantasies of his wife being murdered and soon he developed an obsession that he would lose control and unwittingly stab her to death. These thoughts terrified him so that he developed a fear of knives and other potentially lethal instruments, the sight of which precipitated anxiety attacks. Terror dreams of being cut up and mutilated added to his distress, and he finally begged to have his hands tied to the sides of his bed so that he might not murder his wife in a somnambulistic rage.

It is obvious that mere treatment of the patient's anxiety and other symptoms could accomplish little in correcting the causes of his illness. Actually the patient had received palliative psychotherapy for several years with relatively little improvement. For a while he had taken refuge in religion and had found some solace in the concept of an omniscient deity who might reward his compliance to fate with bounties in the hereafter. During the period of stability that followed it was obvious that his new-found philosophy restored the balance of power that had existed in him as a child reinforcing the defensive structure that had up to the time of his illness kept him free from anxiety. As might have been anticipated, however the deity soon became invested with the ghoulish qualities of his mother and he became convinced that hell's fires awaited him despite his devoutness.

During treatment the same attitudes developed toward the writer, who at first became the embodiment of wisdom and generosity. Slavishly the patient complied with his most casual remarks as if these were edicts he must obey. A complete abatement of symptoms followed for a short while, but as the patient found that his compliance made inroads on his own independent wishes, he began to experience feelings of bitterness, and he accused the physician of having dictatorial designs on him. A return of murder fantasies, anxiety attacks and phobic symptoms almost caused him to interrupt treatment. Painsstaking analysis of his character trends as revealed in his existing relationship eventually led to insight and to a changed attitude toward people and toward himself.

In those cases where symptoms are the outcome of crumbled character defenses, mental stability can sometimes be achieved by restoring the defenses, even though these are neurotically determined. Indeed, where the choice lies between the intense suffering associated with symptoms and neurotic character defenses, the latter are by far the lesser of two evils. One can at least live with a character neurosis, even though one's pursuits must be rigidly circumscribed. On the other hand, it is almost impossible to function with persistent tension and anxiety.

How a restoration of the status quo of a neurotically oriented character structure can produce a disappearance of symptoms was clearly seen in the case of a patient whose depression and hypochondriacal symptoms originated with the death of a parent to whom he was inordinately attached. Unlike other members of the family, who passed successfully through phases of grief and mourning as a result of their bereavement, the patient somehow could not arouse himself from a melancholic outlook. The family physician, a general practitioner, prescribed benzadrine and tonics without avail, and the patient became convinced that he was suffering from a mysterious inner malady which necessitated daily visits to the doctor. These visits consisted of doses of reassurance administered after detailed accountings by the patient of his most minute somatic complaints. It was obvious that he had always been compulsively dependent on his parent, whose departure left him helpless and insecure. As time went on he became more and more dependent on the physician, and soon he entered into a relationship with the doctor of a type identical to his previous relationship with the deceased parent. The physician actually became a substitute parent and psychic balance was restored, with a disappearance of symptoms, until he was forced by relatives to give up his daily visits.

A catering to neurotic character drives is the goal of some forms of psychotherapy which strive to bolster the defenses of the person in order to bring him back to some kind of biopsychic equilibrium. If the patient gets into trouble with people, it is recommended that he operate on the periphery of social relationships. If he must succeed in every task and accomplishment, he might change to an inferior line of work which he can master and perform flawlessly. If he fails as a creative artist, he may be unparagoned as a sign painter. If he has problems in competition then he had better confine his operations to a noncompetitive sphere. If he fears sex, he had best develop interests of a dispassionate nature.

As in therapy directed at the mastery of symp-

toms, this type of treatment, although superficial, may help some patients who are unable to avail themselves of deeper treatment. Thus a homosexual, whose love affairs always terminate in self-destructiveness or homicidal impulses on the basis of feelings that he has been taken advantage of and humiliated, may be assured, with reasonable certainty, that he would probably be more comfortable if he avoided homosexual alliances. He would himself discover, too, that while life lacked a certain sparkle and excitement, he really was better off in the long run if he maintained a detachment from people. However, we must not delude ourselves into thinking that this is the total answer to his problems, for the homosexual drive may really be a frantic groping for some kind of human relationship with a member of a sex who resembles himself and is therefore less terrifying than a person of the opposite sex.

There is always a danger of classifying neurotic character traits as either assets or liabilities, striving psychotherapeutically to foster or discourage them as such. We must scrupulously assay the standards by which we judge traits as either good or bad. The culture enters into our appraisal to some extent, but personal prejudices play a far greater role than we are wont to admit.

The physician should charily regard as assets character traits and drives which, though culturally condoned, are actually at variance with the patient's best interests. As a matter of fact, most patients incorporate within the framework of their neurosis cultural ideals and standards which they believe in some way will resurrect their self-esteem or will enable them to gain love and praise from those they admire. The cultural ideal may be that of ambitiousness or perfectionism or rugged individualism. The patient will misconstrue these ideals, not as means to an end, but rather as ends in themselves. Ambitiousness may thus become a consuming force that drives the person into destructive competitive relationships breeding murderous attitudes toward those who in any way impede his objective of success. He may become tremendously hostile toward his associates and abandon cooperative goals that would contribute to his real happiness and security. Achievement and superiority may become the basis of his whole existence and rob him of opportunities for self-enjoyment. Strivings for perfectionism may cause him to plunge himself into an aimless repetition of details and inhibit him from entering into any form of activity that does not prove his proficiency. The cultural ideal may stress a certain measure of self-sufficiency and individualism. Yet the neurotic will interpret this as a sign that he must resent any intrusion on his own privacy, and his security may hinge upon how successfully he can

divorce himself from others. The culture may perpetuate power strivings, with the result that the neurotic will make strength a fetish and come to despise the slightest weakness in himself or others. The maintenance of an invincible status becomes his sole function in life. To be sick, to fall in love, to yield to the suggestion of anyone else, to fail to foresee the future are considered catastrophic signs of weakness. He may therefore strive to cope in a masterful way with the most inimical situations and shy away from recognizing any limitations in his own abilities or capacities.

Certain cultural ideals may therefore conflict with the attainment of fundamental biologic and social needs. It is essential that the physician understand this since he, himself, may operate under a cherished set of attitudes which constitute for him the highest goal to which any human being can attain. Thus, if he puts too much value in ambitiousness, perfectionism, detachment, dependency, narcissism, or power devices, he is apt to consider these real assets if they happen to appear in his patients. A word of caution must especially be extended toward the group of attitudes collectively embraced under the term of compliance. A reasonable compliance to authority is a necessary thing, but compliance is too often utilized by neurotic persons as a form of security. This is most often the case in those cultures in which the child is a nonentity who is expected to submit himself without question and yield without complaint to the dictates and commands of stronger, more authoritative individuals around him. Where the physician himself, has been reared in an atmosphere that makes compliance an attitude tantamount to good breeding, he is apt to expect the patient to accept his advice and interpretations without protest. The patient may sense this trend in the physician and try hard to please, even at the price of crushing his self-strivings and his need for independent thought and action. The physician may also, because of his own character structure, consider any aggression a sign of recalcitrance and ill will. It is necessary to remember that the primitive emotion of rage is not always a liability and under some circumstances may be a healthier manifestation than a blind submission to authority.

In estimating whether certain character strivings are normal or abnormal, it is essential to consider both cultural and biologic factors. The healthy individual derives pleasure from creature-comforts in life—from food, rest, relaxation, sex, work, and play. He is capable of satisfying these impulses in conformity with the mores of the group and is able to mobilize his intellectual and experiential resources to fulfill his needs.

In every culture the expression of vital needs is subject to some repression, and often there is a direct conflict between cultural and personal standards.

Considering what norms the physician should follow, it is helpful to steer a course somewhere between the Scylla of cultural pressures and the Charybdis of biologic demands. Where the latter conflict with the cultural ideal, it is always essential to have in mind the effect of repression on the individual. On the other hand, it is necessary to adjust the person to the dictates of society, helping him to develop technics through which he can satisfy his biologic needs in a culturally condoned manner. For example, while the ability to express oneself sexually is a physiologic aim, it might be disastrous to the individual to advise that he indulge himself sexually without satisfying certain social requirements and standards.

In general, the objective most-consistent with mental health is a personality which effects a harmonious balance between personal and group standards, between cultural and individual ideals. This presupposes the expression of adequate and realistic goals that contribute both to the welfare of the self and the group.

Perhaps the best criterion of progress during treatment is an improvement in interpersonal relationships. This improvement is a prime objective in therapy. The individual must be able to relate oneself congenially to his fellow creatures, to give and to receive love without indulging neurotic character strivings in the form of detachment, needs to dominate or to be enslaved, or desires to render himself invincible or perfect.

He must be able to assume a subordinate relationship to authority without succumbing to fear or rage. He should, in certain situations, be capable of assuming leadership without designs of control or power. The well-integrated person should be able to withstand a certain amount of deprivation and frustration without anxiety when he feels these are reasonable, are shared, are necessary to the group welfare, or when consequences of impulse indulgence entail more than their worth in compensatory pain. His capacities for adjustment must be

of defense or in fantasy.

A further objective is a healthy regard for himself as an individual. This embraces self-knowledge, a willingness to face the past and to isolate anxieties relating to childhood experiences from the present. It involves a realization of his limitations and the ability to fulfill himself creatively within the bounds of these limitations.

It includes self-confidence, assertiveness, a sense of freedom, spontaneity, and self-tolerance.

Unless these objectives are achieved through psychotherapy, the dynamic framework of the neurosis remains untouched, and while the individual may make a tolerable adjustment to life, he will be unable to live up to his full capacities and aptitudes. He will be at the mercy of unconscious fears and impulses which will necessitate perpetual defenses and needs for control. He will be victimized by compulsive character drives which induce distortions in his sense of values and make the normal pursuits of life vapid and meaningless.

### Summary

Emotional illness represents a collapse of the psychic resources of the individual when he is unable to fulfill biologic impulses and social demands. The immediate consequences of this collapse are symptoms which constitute the various manifestations of neuroses. Goals and objectives of adequate psychotherapy involve not merely a dissipation of symptoms, but a reintegration of the patient as a working unit in society to a point where he can function successfully in his relationships with the others. This necessitates a careful inquiry into neurotic character drives which must be scrupulously uprooted, even though they are imbedded in what seem to be culturally condoned attitudes and values.

The physician should investigate carefully the standards by which he judges the patients' strivings as either assets or liabilities. This is necessary to avoid pandering to the patients' neurotic traits, reinforcing them at the expense of vital biologic and social needs.

The criterion of a real mental cure lies in a replacement of neurotic character strivings with those which will enable him to relate himself productively and creatively to his environment. This objective must be reinforced by liberation of the individual from anxieties and fears that are rooted in past experiences and conditionings.

Mental health presupposes self-growth and development of the ego to a point where it can cope realistically with inner strivings and environmental pressures. The individual must evolve into a free moral agent who has the ability and willingness to make his own decisions and to take the consequences of his own acts. There must be an adaptive choice of ends and means and an ability to act without undue restraint from others. Capacities to plan one's life and to develop goals and ideals in harmony with the disciplines of society are vital. A sense of inner freedom, independence, assertiveness, and self-reliance are other requirements of a well-balanced personality.

Unless these objectives are fulfilled in psychotherapy the person will be incapable of functioning efficiently in his complex social environment

and will be at the mercy of tensions and anxieties which eventually may induce a relapse of emotional illness.

## WILLIAM HARVEY (1578-1657) AND THE VALVES IN THE VEINS

Shortly before William Harvey died, Robert Boyle, the versatile natural philosopher, betook himself to call upon the aged physician to ask what had led him to the discovery of the circulation of the blood. Boyle was then in his middle or late twenties, and Harvey was approaching 80. In a philosophical discourse on other matters Boyle gave the following account of the famous interview:

"I remember that when I asked our famous Harvey, in the only Discourse I had with him (which was but a while before he dyed) What were the things that induc'd him to think of a *Circulation of the Blood*? He answer'd me, that when he took notice that the Valves in the Veins of so many several Parts of the Body, were so Plac'd that they gave free passage to the Blood Towards the Heart, but oppos'd the passage of the Venal Blood the Contrary way: He was invited to imagine, that so Provident a Cause as Nature had not so Plac'd so many Valves without Design: and no Design seem'd more probable, than That, since the Blood could not well, because of the interposing Valves, be Sent by the Veins to the Limbs; it should be Sent through the Arteries, and Return through the Veins, whose Valves did not oppose its course that way."

This statement is indeed significant, and I believe it gives the clue not only to the epic discovery, but also to the real basis of Harvey's contribution to scientific medicine. Many others had seen the valves in the veins, but no one had paused to inquire into their functions by means of experiment. Prior to Harvey, to be sure, there had been speculation from the pens of those who had also observed these structures. Salomon Alberti, who gave the first illustration of a venous valve (1585), interpreted their probable function in terms of the Galenic concept of the circulation, as did also Harvey's master, Fabricius ab Aquapendente, in his monograph "*De venarum ostiis*" (1603), recently translated into English by Dr. K. J. Franklin.

The story of Harvey's life is known only in outline, but such details as have come down to us are highly significant. Born at Falkstone on April 1, 1578, the eldest of nine children of Thomas Harvey, a Kentish yeoman, he entered Cambridge University in May, 1593, graduated with the B.A. degree in 1597, and ultimately became a Fellow of Gonville and Caius College. Late in life he also passed a year or two in Oxford (1645-1646) as Warden of Merton College.

After obtaining his B.A. in 1597 from Cambridge, Harvey, like Thomas Linacre one hundred years earlier and John Caius some fifty years before, repaired to Italy where he remained for five years,

passing the greater part of his time at the University of Padua under the influence of the distinguished anatomist, Fabricius ab Aquapendente. Harvey took a medical degree at Padua on April 25, 1602, and the celebrated Harveian "stemma"<sup>1</sup> is still to be seen in the *Aula Magna*. During his years at Padua Fabricius frequently demonstrated to his classes the venous valves which he so fully described in the monograph published shortly after Harvey had departed. On returning to England Harvey apparently meditated upon his experiences with Fabricius and, probably in 1609, began a series of experiments which ultimately led to the great discovery.

Meanwhile he was "incorporated" M.D. at Cambridge in 1602 and was elected a Fellow of the College of Physicians on June 5, 1607. Two years later (October 14, 1609) he attached himself to St. Bartholomew's Hospital as "Physician to the Hospital." He received an Oxford M.D. on December 7, 1642.

In his Lumleian lectures given to the College of Physicians in April, 1616, the notes of which are still preserved, he first gave the essence of the discovery in the following cryptic language:

"On account of the structure of the heart, William Harvey is of the opinion that *the blood is constantly passed through the lungs into the aorta, as by two clocks of a water bellows to raise water*. Moreover, on account of the action of a bandage on the vessels of the arm he is of the opinion that *there is a transit of blood from the arteries to the veins*. It is thus demonstrated that *a perpetual motion of the blood in a circle is brought about by the beat of the heart*. What shall we say? Is this for the purpose of nutrition? Or is it for the better preservation of the blood and of the members by imparting heat to them, the blood by turns losing heat as it warms the members, and gaining heat from the heart?"

Here is the essence of the discovery: "There is a transit of blood from the arteries to the veins." It was announced formally to the world in 1628 and it now seems clear that Harvey was led to make this great scientific deduction through having recognized the significance of the valves in the veins.

Undoubtedly there are many other discoveries "just around the corner" for those who are willing to appraise by means of experiment structures of unsettled use.—John F. Fulton, M.D., in *North Carolina M. J.*, May, 1944

<sup>1</sup> Denoting that in 1600 he stood as Councillor for his fellow English students—"The English Nation," as groups in the student body at Padua from a given country designated themselves.

# THE COMMON COLD\*

HARRY ADLER, M D , Elmira, New York

THE common cold is a major medical and economic problem Piersol<sup>1</sup> and others report that 50 per cent of sickness-absenteeism in industry is due to acute infections of the upper respiratory tract However, one can only approximately estimate the amount of time lost from work as a result of a cold, and one will find it difficult to estimate the extent of suffering and hardship caused by the common cold, to say nothing of the countless millions of dollars spent by the public in its futile effort to obtain some relief

Consideration of the common cold has received a great deal of space in almost every publication imaginable A feeling of futility still confronts the physician when he is called to the bedside to treat the patient with a common cold He is aware that he does not have at his disposal a proper therapeutic agent or an accomplished procedure more effective than bed rest

The public has been either misinformed or not properly informed, and consequently, self-treatment and care in many instances are harmful There is an attempt in industrial medicine and in public health to bring home pertinent facts and rules However, such publications<sup>2,3</sup> should avoid statements that can be misunderstood, for such misunderstanding is bound to lead either to neglect of treatment or to incorrect application of it For example, one might question the advisability of stating that "in most instances, of course, special medical treatment for colds is unnecessary" Patients have been frequently told to use as treatment an abundant supply of handkerchiefs Patients are being advised as routine therapy to use laxatives and large amounts of alkaline drinks This form of therapy forms the basis of many extensively advertised commercial products It may be theoretically correct to say that a common cold is self-limited and of itself is of little consequence Observation compels us to seriously question the accuracy of this statement, and it is our impression that therapy is more apt to be improved when we refuse to accept any disease as being self-limited We quote Piersol "when lay and professional apathy toward the consequences of minor illnesses shall have been overcome, a definite beginning will have been made toward the control

of acute respiratory-tract infections and their sequelae"

The confusion of thought as to the cause and management of the common cold prompted me to undertake a study of the current literature in this field and to try to provide a more rational approach to its management

Kerr and Lagen<sup>4</sup> define a common cold as an acute inflammation of the nasal mucous membrane with general constitutional manifestations

Discussion of the causation of the common cold can be broad in scope Many authors believe that the offending agent is a filtrable virus Turner<sup>5</sup> made an interesting observation on normal children when they were exposed to childhood diseases Many who did not come down with the disease to which they were exposed came down instead with symptoms of upper respiratory infection This was also observed among adult teachers Thus, there arises the possibility that many organisms may be the cause However, a great deal still remains unexplained about causation Is an organism always the primary of sending agent? Kerr and Lagen, Hamilton,<sup>6</sup> Walsh,<sup>7</sup> Stewart,<sup>8</sup> Spavens,<sup>9</sup> and Goodyear,<sup>10</sup> lay stress on the role that chilling plays in causing colds Kerr and Lagen argue that repeated trauma to the mucosa by sudden changes in temperature is a factor, along with lowered body resistance, and that the result is a breakdown of the delicate layers of the nasal mucosa—the typical picture of inflammation in which the presence of bacteria or virus need not necessarily be assumed However, the injured tissue provides a suitable culture medium for secondary invaders The same authors also stress as causative factors fatigue (mental and physical), overeating of one or many types of food, anatomic defects, presence of foci of infection, constitutional illness, dietary insufficiencies, exposure to hot air, and emotional disturbances, as reported by Spiesman<sup>11</sup> Walsh<sup>7</sup> reports that the cilia function most effectively at 32 to 60 F At 72 F they are retarded and at 78 F ciliary action ceases It is, therefore, apparent that people, as far as possible, should avoid room temperatures above 72 F during the cold months Stewart considers as a causative factor the daily intake of moderate amounts of any fruit juices—this cause we believe to be important because of the excessive use of fruit juices in the present-day quest for "increased resistance" and vitamins He also lists as a cause hyperventilation Hyperventilation is more apt to be ha " " dur

\* This study was conducted by the author The administration of treatment and the collecting of the statistics were done by the staff of the Hospital of the Elmira Reformatory—Editor

sleep. There is no doubt that, in a search for fresh air, the people have adopted another fad. There is, therefore, need that the public be better informed of proper health precautions against the common cold.

Review of the physiopathology of the nasal mucosa is essential to a better understanding of the phenomena accompanying the cold. It is important to note that a rich capillary system is distributed throughout the connective tissue of the mucosa, and that around the ducts of the glands, the mouths of which usually lie in some sulcus of the surface epithelium, there is an especially rich network of capillaries. It is seen, then, that vasomotor dilatation of these capillaries must result in considerable constriction of the outlets of the glands and at the same time would produce serous exudation through the mucosa into the nasal cavity. As the vasomotor excitement subsides, this constriction is released and free discharge of the contents of the mucous glands is allowed. It is said that the secretion from the racemose glands of the respiratory part of the membrane is in itself considerably bactericidal. These views are held by Lillie<sup>12</sup> and Fox.<sup>13</sup> However, Lillie further states that the watery discharge during an upper respiratory infection is not bactericidal in action.

and Fabricant<sup>14</sup> report that the normal pH 5.5 to 6.5 changes to alkaline during acute rhinitis. We thus are confronted with a deranged physiologic process, the sequelae of which are the typically subjective complaints of the patient: to wit, general malaise, head fullness, and the irritating nasal discharge, all of which typify acute coryza.

From a clinical standpoint the nasal discharge is the most important. It now provides a seemingly excellent medium for the growth of bacteria. With and following bacterial invasion this originally watery exudate now becomes mucopurulent and its extension, either by blowing or sneezing, carries the infection not only to the accessory sinuses, eustachian tubes, etc., but also into the atmosphere, where it is the vehicle by which contagion is spread. Furthermore, the presence of any nasal discharge interferes with normal ciliary action, nullifies the usual bactericidal properties of the normal nasal secretions, and prevents medication introduced into the nose from making direct contact with the tissues themselves, and when cold air enters the nasal cavity this watery nasal discharge quickly becomes chilled and in turn further intensifies the chilling of the underlying tissues. It is highly probable that the disorganized physiologic activity of the mucosa and submucosa lowers their resistance against a deeper invasion of the organism.

At present we are not in complete accord about the relationship between causation and physiology. Some authors place emphasis on the chilling and the resultant disturbed process. Other authors believe that the disturbed process follows the invasion, be it virus or bacterial. We may, however, surmise that the vascular engorgement and the invasion phenomena are so closely related that, for practical purposes, the two phases may be considered to occur simultaneously.

In focusing our attention on treatment we are confronted by two problems. We must combat the bacterial or virus invasion and the engorgement. The phenomenon of engorgement results primarily from a disturbance of normal physiology. Treatment should then be aimed at restoring the tissues and their function to a normal state or balance. Thacher and Hauser<sup>15</sup> experimented along this line in treating patients with hypertrophic rhinitis with submucosal injections of sodium morrhuate. They reported that postnasal dripping diminished and that headache and head fullness subsided. To date, various treatments have been used in an attempt to achieve a variety of objectives. Some of these treatments, however, do not appear to have been considered in the light of current physiologic concepts.

Williams<sup>16</sup> condemns the indiscriminate use of vasoconstrictors as practiced by the public, because of the nasal congestion as a result of the secondary and refractory relaxation that follows the primary constriction. Cowan<sup>17</sup> reported that benzedrine used to shrink mucous membrane as an abortive for colds, in an experimental series, produced negative results. Walsh, in condemning most nasal applications, states that medications in oil are too heavy for the cilia, mix poorly with mucus, and thus barely reach the epithelium. Hypo- or hypertonic watery solutions cause destruction of cilia, and ephedrine causes almost immediate cessation of ciliary function. One per cent commercial silver preparations do chemical injury to cilia, and bacteria which have been in these solutions forty-eight hours are still viable. Williams<sup>16</sup> and Lillie<sup>18</sup> object to nasal drops or sprays of constrictors because they help carry infection from nose to pharynx and below. It would seem, then, that the immense amount of vasoconstrictors used by patients is a serious consideration because of the harm done.

The profession, in need of a good therapeutic agent, received vaccine therapy very enthusiastically because the first reports were favorable. Smillie,<sup>2</sup> Diehl,<sup>19</sup> Hauser,<sup>20</sup> Stafford,<sup>21</sup> Hamilton,<sup>6</sup> Stanley,<sup>22</sup> and Holbrook<sup>23</sup> conducted various studies on the use of vaccines, and these studies

lead us to several conclusions. Persons who have received vaccines as a prophylactic either by hypodermic or by mouth report that they had fewer colds. However, others who received placebos reported the same degree of improvement. It is interesting to note that many in the placebo group were so impressed by the results that they returned the next year for another course of what they thought was cold vaccine.

If we consider the filtrable virus as a cause of the common cold, we then raise a question as to the value of bacterial vaccine as an immunizing agent against a virus, and how we can expect the vaccine to influence the onset of colds. However, if we consider bacterial invasion as a secondary invader, we can approach vaccine therapy from a different aspect. The question arises, can we expect vaccine therapy applied during the illness to confer immunity against the secondary bacterial invaders and thus curtail the unpleasant complications? The literature about the use of vaccines during the course of the cold is meager. We are using the vaccines in catarrhal otitis media and have found this treatment highly useful in avoiding purulent otitis media. In chronic upper respiratory and tracheobronchial infections we found recovery definitely hastened. However, our results in the latter group are not consistent. There is a possibility that a stock vaccine may have too few organisms for a particular patient. Epidemics vary and the organisms involved also vary from time to time. Walsh<sup>24</sup> conducted experiments with animals and, after observing anatomic changes in the mucosa caused by vaccine sprays, felt that this procedure might be of value to humans, and reports apparent good results in a study of its use in humans. We thus come to the conclusion held by several writers, that vaccine therapy is efficacious if applied properly and under certain conditions.

There are other studies and reports worthy of mention. Cantor and Berman<sup>25</sup> advocated the use of a suction syringe to aspirate nasal discharge in children. This remedy is of value in aiding removal of some of the obstruction and affording temporary relief. Dolowitz<sup>26</sup> used Pickrell's solution (sulfadiazine solution) as a spray on a group of nurses who had colds in the early stages, and observed fewer complications in the treated group than in a control group. Turnbull<sup>27</sup> used a similar solution with similar results. The recent popularity of vitamins has resulted in including these substances as agents for the prevention and treatment of colds. Spiesman,<sup>11</sup> in his study, used massive doses of vitamins A and D and obtained negligible results. Cowan<sup>19</sup> and his group used vitamin C and concluded that the fortune spent on vitamin C as a cold

preventive was not justified. Cowan,<sup>17</sup> in other studies, used benzedrine as an abortive and in another study used codeine-papaverine mixture. In both instances the results obtained in the treated and control groups were similar. Rawlins<sup>28</sup> used sulfur dioxide gas on 80 patients, 66 were appreciably aided. Those who had had a cold three to four days were not helped. However, it is difficult to recommend sulfur dioxide gas for routine use, for obvious reasons. Siegel<sup>29</sup> used sulfadiazine in acute respiratory infection and observed that "signs of infection, such as coryza, still persisted in many cases, but that the infection appeared to be subsiding as if the inflammation had abruptly passed the acute stage. Those whose temperatures remained below 102 F usually did as well as the treated group."

The work of Siegel and others brings forth several observations.

It is not advisable to use sulfadiazine routinely in colds.

The distressing symptoms of coryza are in part due to physiologic disturbance.

Our approach to relieving symptoms of coryza need not be an antibacterial one, although as yet we have made no other type of attack.

True, we have made some slight progress in combating complications by the use of either vaccines or chemotherapy. We maintain, with Fox and Fabricant, that the patient with a cold is distressed by the marked exudation which follows the engorgement of the nasal mucosa.

We are, therefore, confronted with the necessity of providing relief from this condition to patients who are distressed during the early stages of coryza, and our course should take into consideration certain physiologic principles. We searched for an agent compatible with most medication easily administered, nontoxic, and that it would avert or relieve tissue engorgement—this latter being one of our principal objectives. Sodium chloride seemed to possess most of the desired properties.

It is therefore pertinent to consider the chemistry and the physiology of sodium chloride in the tissues and to study the effects of ingestion of large doses of it.

Sodium chloride is reduced to sodium and chloride ions in the tissues, and when the ions are increased in the extracellular tissues, there results a flow of fluids from the cells to the extracellular tissues. This is a simple osmotic principle. The fluids then gradually follow the sodium ions to the blood and thence to the kidneys.\* The withdrawal of fluids from the cells

\* Any reader desiring greater details concerning sodium chloride chemistry is referred to Cantrill's<sup>30</sup> fine monograph.

of the nasal mucosa is therefore bound to cause a decrease in secretion from the glands and from the mucous membrane of the nose. Physiologically, sodium chloride administration, with its resulting decrease in exudation, does not interfere with ciliary action, does not interfere with bactericidal properties, averts further chilling of nasal tissue, the formation of a favorable medium for bacterial growth, nasal obstruction, and fullness of the head, and permits close contact between medicinal sprays and the mucous membrane, and, finally, averts spread of the infectious exudate to other tissues.

The next logical step was a study of the toxicity of large amounts of sodium chloride. Cutting<sup>31</sup> administered to animals lethal massive intravenous infusions of sodium chloride. He found that recovery is complete if the infusion is stopped before death—that is, before the blood pressure begins to drop—that the cerebrum is the only organ that does not store water, and that within twenty-four hours all salt is excreted. Trusler<sup>32</sup> reported that the adult body contains about 300 Gm. of salt and that about 25 to 30 Gm. are in the blood. Gamble gave a group of patients 20 Gm. daily for three days. By the third day the kidneys had regained control of the salt and water balance. He also stated that total change in extracellular sodium electrolyte is  $\frac{1}{10}$  of normal during this experiment. Salt has recently been more and more recognized as an essential constituent of our daily food intake. The ingestion of large amounts of sodium chloride for a short period is not harmful.

In our institution the first group of patients who received salt treatment rendered subjective reports that were more favorable than was anticipated. Patients stated that they could breathe through the nose with more ease and that secretion diminished markedly within an hour after the ingestion of salt. This decrease was followed by improvement in the feeling of fullness of the head. As a further improvement, sneezing and nose-blowing became much less frequent and general malaise was reduced. Goodyear<sup>10</sup> made a similar observation, apparently, when he stated that "table salt will abort a cold quicker than most remedies."

Our first group of patients who were given salt had a short period of relief. We then proceeded to increase our dose and to repeat the dose at definite and variable intervals. Patients observed that the drying effect upon the nose lasted from eight to twenty hours. The drying effect was apparently dependent upon the severity of the infection. In very severe infections cessation of exudation and relief lasts about ten hours. A second dose given in ten hours in severe cases prolonged the period of relief which the patient

had previously experienced. When some early cases were given sodium chloride and obtained relief for twenty hours and then medication was stopped, we observed that the coryza returned with about the same severity as in the instances of the untreated patients. We therefore concluded that the severity of an infection cannot be judged by the relief obtained from the first dose and that medication must be continued. After experimentation and observation we adopted a routine for our hospital. A daily dose is given for three days. It consists of 1 ounce of a saturated solution, approximately 10 Gm. of salt. The exceptional patient who wishes the best results, regardless of epigastric distress of short duration, should take a second dose ten to twelve hours after the first dose, a third dose in twenty-four hours, and a fourth dose in forty-eight hours. We have administered sodium chloride in 8 Gm. doses to children without untoward reactions and with excellent results. This form of therapy is not recommended routinely for undisciplined children because of the difficulty of administration and the fact that the child may not retain the medication.

We have observed that patients who failed to report for a second treatment became sick again on the third day and offered the explanation for failure to report that they thought they were cured. However, if one finds the improvement marked, the patient can then decrease the amount of the second dose, but should not omit it entirely. Patients who apparently have come down with a very severe acute coryza will still have some exudation during the first few days and on the fourth or fifth day the nasal discharge may become mucopurulent. In those instances we repeat one dose, and sometimes two doses, during the latter stage and have observed that recovery becomes very noticeable after the therapy. The most important recommendation we offer is that a cold must be treated at the earliest possible moment. If treatment is delayed it is still effective, but not so dramatic as if it had been administered early.

There are several comments relative to the administration of sodium chloride that are worthy of note.

Practically no incompatibilities arise from its use. However, the gastric mucosa in some persons is sensitively reactive, resulting in nausea or epigastric distress and even occasionally in vomiting. We have observed that the administration of sodium chloride one to two hours after meals markedly lessens any untoward gastric reactions. There is a severe thirst that follows salt ingestion and it is recommended that only small amounts of water be given merely to partially quench the thirst. For obvious reasons

salt is not recommended for patients who have frequent gastric complaints, and during the administration a patient should partake of a soft diet. All other reactions experienced are mild and transitory.

We were so impressed by the efficacy of this form of therapy that we adopted it routinely and then decided to make further studies and observations as the occasions arose. In our first study we attempted to have the patients compare the results of other treatments to the results obtained from salt therapy.

We observed that the memory of patients was too unreliable and such conclusions would therefore be inaccurate. In another instance we obtained cultures from the nose of patients before and after treatment and had a report of the number of colonies after the material was cultured. Although the results were favorable, they were not consistently so and therefore these results were discarded. It then became apparent to us that no matter how impartial one may be, a single study concerning the treatment of a cold can easily appear, on the surface, to be misleading. We made several attempts to inform our inmate population to report to "sick call" at the first signs of a cold. We observed that as a result of their indifference to the common cold they usually neglected to report for treatment until the second or third day of the cold. After we observed many such instances and accepted salt as good therapy in the early stages we then decided to treat all colds similarly and to record our treatments.

We felt that a study of several thousand cases over a period of years would provide more accurate information than the study of a single group, and for that reason we reviewed our hospital records for a period of four years.

There are several factors to be borne in mind in our study. We are dealing with an inmate population to whom routine is distasteful and "sick call" visits provide an opportunity to depart from routine. Therefore, a patient may come to "sick call" repeatedly for a cold. It has been our policy that a patient who claimed he still had a cold, in spite of salt treatment for three days, was hospitalized. Although this patient was not sick, he was included with the others who failed to respond to salt treatment.

As we have stated above, salt treatment is more effective if administered within the first few hours of onset of the cold. Patients who reported several days after the onset also received salt, and failures in treatment of this group were also included in the study. The patients' common explanation for failure to report early was that they "thought the cold would go away of its own accord." We conducted a study for one

TABLE I

Year	Type of Therapy	Number Treated	Number Hospitalized	Percentage of Group	Average Temperature
1940	Standard	550	13	2.36	100.2 F
	Salt	150	2	1.74	102 F
1941	Standard	162	13	8.02	99.6 F
	Salt	213	16	7.05	99.4 F
1942	Standard	103	3	2.94	99.4 F
	Salt	366	6	1.6	98.7 F
1943	Standard	557	8	1.4	98.9 F
	Salt				

month (March 2-April 2, 1943) on 37 men who complained of either a running nose or nasal stuffiness. They were treated with our routine salt therapy. Most of them had their illness twenty-four hours or less. In none of these patients was bed rest indicated within the five-day period after treatment had been instituted.

Analyzing our clinical records, which now contain considerable material, we have been able to come to some fairly clear cut conclusions. We studied our outpatient clinic records and compared them with our hospital records. We wanted to know how many men who received treatment for a cold were admitted to the hospital within four days after treatment had begun and how sick these patients were. A patient was routinely admitted to the hospital who had an oral temperature of 100 F or over at "sick call," or whose symptoms suggested gripe, or who claimed he had not improved after receiving ambulatory treatment.

We divided our patients into two groups. Those who received salt treatment were called the "salt group"; those who received accepted forms of treatment were called the "standard group."

To measure severity of infection we recorded the highest oral temperature during the hospital stay and in group studies used an average (see Table I).

We can view this study from another aspect. Of the men who received treatment and were admitted to the hospital, there were 29 who received standard treatment, 15 of that group had a temperature of 100 F or over. In the group of 32 who received salt treatment before admission, 9 had a temperature of 100 F or over. The average temperature of the entire standard treatment group was 100.05 F. The average temperature of the salt treatment group was 99.3 F. The average hospital stay of the standard group was 3.69 days. The average hospital stay of the salt group was 2.9 days. Thus, out of 1,686 who received salt, 32 were hospitalized—a percentage of 1.9. Of 415 standard-treated patients 29 were hospitalized—a percentage of 6.9.

A few observations and inferences of practical value can be drawn from our hospital study.

Patients who received salt treatment within the first twenty-four hours of the onset of the cold avoided hospitalization and thus avoided losing time from work. Second, those who received salt treatment more than twenty-four hours after onset of the infection had a milder illness and spent less time in the hospital as compared to the standard-treatment group.

In 1940, 95 men were admitted to the hospital. Their average high temperature in the hospital was 100.1 F. The salt treatment was begun in the late fall of 1940 and was routine for the first half of 1943. Fifty-one men were admitted to the hospital for the first half of 1943 and had an average high temperature of 99.3 F. This trend has been gradual since 1940 and may be an indication that improvement in cold treatment lowered the infectiousness of the organisms.

Progress is usually associated with experimentation. In spite of the fact that we felt we had a "promising" therapeutic agent at our disposal, we felt that there was still a great deal of room for improvement. It is generally accepted that heliotherapy is a valuable adjunct to the improvement of a patient's immunologic powers. We therefore decided to add heliotherapy to salt treatment. The subjective and objective results of ultraviolet therapy were such that we now feel that we have another valuable therapeutic agent in the treatment of common colds. We are, therefore, attempting to include ultraviolet therapy routinely in the treatment of colds; the only obstacle is the shortage of equipment as a result of the war. Incidentally, it has our experience that ultraviolet therapy is of value as a prophylactic agent.

For ultraviolet radiation we use a mercury vapor apparatus at a distance of 36 inches, allowing for three-minute exposure each to the front and back of the chest for the first treatment. We increase the time of exposure by one minute daily, naturally allowing for individual tolerance to ultraviolet.

In addition to salt, heliotherapy, and vaccines in certain selected cases, we use a nasal spray of sulfadiazine solution (Pickrell solution). This spray is not harmful to the nasal mucosa and, as reported by Turnbull and Dolowitz,<sup>26</sup> is helpful in combating the secondary invaders.

## Summary

The common cold is of tremendous importance clinically and economically. Outstanding factors that predominate as causes of the common cold are chilling, with its accompanying alteration of normal physiology, and bacterial and virus invasion. There are many forms of treatment

and recommendations, and the majority of them are either useless or harmful. Two notable exceptions are the use of vaccines in proper instances during the course of illness and the use of sulfadiazine solution spray.

Accumulated evidence sustains the contention that engorgement of the nasal tissues and the coryza syndrome that accompanies it account principally for the discomfort of the patient and for the failure of what has been accepted as standard treatment. It then follows that any treatment that tends to restore tissue to approximately its normal state should be the treatment of choice. We believe that the use of sodium chloride by mouth in the common cold is that type of treatment. Sodium chloride in large doses abruptly curtails marked serous exudation and thus contributes to the comfort of the patient, shortens the course, lessens the severity, markedly reduces absenteeism—all this in contrast to the simplicity of the medication.

# CORRELATION OF PERITONEOSCOPIC FINDINGS WITH CLINICAL AND PATHOLOGIC FACTORS, ESPECIALLY OF THE LIVER

LEONARD PAUL WERSHUB, M D , F A C S , New York City

WHEN Max Nitze, in 1877, first tried to introduce the cystoscope as a universal diagnostic method he was awarded with an abundance of adverse criticism and resistance. In fact, thirty years elapsed before cystoscopy was generally recognized, although the many technical objections had already been eliminated. Similarly, the procedure now known as peritoneoscopy was first reported in 1901 by Kelling of Dresden, who termed it *Zoelioskopie*, but more than thirty years elapsed before any real recognition was given to this procedure. Here, too, delay in acceptance was in part attributed to technical difficulties and objections which ultimately were overcome by Ruddock of California. But there still remain many who, without evaluation of the procedure, condemn it. Others who are not familiar with it accept it as a means of diagnosis when all other methods are of no avail. They subsequently condemn it for its shortcomings.

Those who are familiar with peritoneoscopy and have learned the scope of its usefulness by prolonged application and study are still enthusiastic and realize that except for laparotomy peritoneoscopy is the only procedure that provides a direct method of examining the peritoneal cavity and its contents.

It permits the experienced peritoneoscopist to inspect the presenting surfaces of the liver, gall-bladder, stomach, spleen, omentum, intestines, pelvic viscera, and parietal peritoneum. The peritoneoscopist has learned that the procedure is of no value if used indiscriminately, and should only be performed for a definite purpose. The error of accepting cases for diagnosis has undoubtedly led many to belittle the value of this procedure and to erroneously classify the procedure as unscientific. The limitations must be clearly understood, and, above all, the findings of a negative examination must be properly interpreted. If a specific request or purpose of examination is defined then the examination is justified. It will aid in either confirming a diagnosis or establishing a diagnosis.

To repeat, the value of peritoneoscopy is in direct proportion to a proper understanding of the limitations of peritoneoscopy. Since only the

anterior surfaces of the accessible viscera can be seen, no value can be given to the interpretation of lesions occurring in the posterior surface of organs. It certainly cannot be applied to lesions of organs which cannot be seen by the endoscope. The value of the examination depends entirely upon whether the organ in question is in the field of vision. Thus if a patient has ascitic fluid, with loss of weight and laboratory findings not particularly significant of hepatic disease, and peritoneoscopy is requested, the operator confines himself to visualization of the liver. If the structure appears normal, he can say the ascites is not due to cirrhosis and even if he goes no further he has accomplished his purpose and aided in the diagnosis. Should the liver appear cirrhotic, then he has given a positive finding. A negative finding does not necessarily rule out pathologic changes, but merely eliminates the organ in question.

A peritoneoscopy service was originally formed to study the problem of peritoneoscopy and its relation to a large general hospital such as we have at the Metropolitan and Flower-Fifth Avenue Hospitals. Since this organization was started the patients so examined now number 142. A review of the first 100 of these cases will form the basis of this report. These patients have been from the various services, but the majority have come to us from the so-called "study group" of the medical department and the remainder from the surgical service. Those cases presenting cirrhosis have been hospitalized for progressive studies, and whenever feasible have been maintained in the research group at the Metropolitan Hospital. This has permitted extensive investigation pertaining to hepatic disorders and associated laboratory data.

In an analysis of 100 cases (Table 1), 66 cases were encountered which were directly related to the gastrointestinal tract. Of these 54 were related to the liver. Let us first consider cirrhosis of the liver, of which 35 cases were encountered in this series.

Cirrhosis of the liver, particularly in the compensated stage, is exceedingly difficult to diagnose accurately. In many instances the disease is latent and unsuspected and frequently is accidentally recognized at the surgical table or at the postmortem examination. The disease is suspected when a diagnosis of alcoholism and multiple gastro-enterologic symptoms are obtained. But alcoholism may exist without cirrhosis of

the liver, as cirrhosis of the liver may occur without a history of alcoholism. The disease is always suspected when an esophageal varix ruptures. Hematemesis is an initial symptom and practically diagnostic, but is not an early symptom. It is usually followed by the stage of decompensation accompanied by jaundice or ascites.

As a rule, cirrhosis of the liver is more easily detected during the stage of decompensation or phase of ascites, but here, too, difficulty in diagnosis is encountered. Palpation of the liver as an aid in diagnosis has been pointed out by many workers to be unreliable. We have had the experience of checking the bedside opinion of competent observers with endoscopic study and too frequently have been unable to visualize the so-called "nodular or granular" feel of the liver or the "enlarged liver 4 to 5 fingerbreadths below the costal margin." Our findings have been confirmed by subsequent laparotomy and necropsy in a large percentage of our cases.

Even the presence or absence of ascitic fluid may be of little aid to the clinician. If present it may merely confuse the picture. It is not uncommon for us to peritoneoscope a patient and withdraw 2,000 cc. of fluid which had not been on the records prior to peritoneoscopy.

In view of the many shortcomings in clinical diagnosis of cirrhosis of the liver, peritoneoscopy offers an easy and direct method of examining the liver for diagnosis. By this method direct endoscopic visualization of the liver is possible, and in the hands of the trained observer a definite diagnosis can always be made in the portal type of cirrhosis. In many cases of ascites or hepatomegaly of unknown origin it is the only diagnostic method other than laparotomy.

The next entity which I will discuss is carcinoma of the liver. The occurrence of cirrhosis of the liver as an associated lesion of primary car-

cinoma of the liver has been emphasized by many writers on this subject. In our series we found no such correlation and only encountered 15 cases of carcinoma, all secondary to a lesion elsewhere in the body. Secondary carcinoma of the liver is relatively common, being twenty times as prevalent as primary carcinoma of the liver. As a rule, the disease may be suspected when there is a rapid increase in liver size, a nodular surface, local tenderness, and extreme cachexia. Since the symptoms are frequently identical with those of cirrhosis of the liver, it is often difficult to clinically differentiate the disorders unless the primary site has been determined and metastasis is suspected. In this respect it should be remembered that in approximately one-half the cases of metastatic carcinoma of the liver the primary site cannot be determined during life. The peritoneoscopist can distinguish between cirrhosis and malignancy, and in the latter group can frequently determine the site by biopsy studies, which obviates the necessity of exploratory laparotomy.

Another interesting entity is primary carcinoma of the gallbladder. Like primary carcinoma of the liver, it is not so common as secondary malignancies and is extremely difficult to diagnose clinically. It is generally associated with gallstones and is more common in females than in males. Because of difficulty in diagnosis it is probable that it is more prevalent than available statistics, which place it as occurring in 3 to 5 per cent of all cancers, show. Here peritoneoscopy is offered as a further aid in diagnosis, since laboratory tests are of no avail and only in occasional instances will roentgenographic studies suggest the diagnosis. In our series one case of primary carcinoma of the gallbladder was encountered.

### Summary

To summarize: I would like to leave the following impressions concerning the use of the peritoneoscope and its use as it concerns diseases of the liver and gallbladder.

1. The peritoneoscope has specific indications for its use. The indications previously expressed are definite and in some cases offer the only means other than exploratory laparotomy for diagnosis.

2. The diagnosis of portal cirrhosis which so frequently cannot be accurately determined can be made with 100 per cent accuracy by the peritoneoscope. In other hepatic disorders the endoscopic impression may confirm or establish a diagnosis.

## BASIC CONCEPTS OF ALCOHOLICS ANONYMOUS

WILLIAM G. WILSON,\* New York City

**A**LCOHOLICS Anonymous is an informal fellowship of about 12,000 formerly alcoholic men and women who are to be found banded together as groups in about three hundred and twenty-five American and Canadian communities, these groups ranging in size from half a dozen to many hundreds of individuals. Our oldest members have been sober for from eight to nearly ten years. Of those sincerely willing to stop drinking about 50 per cent have done so at once, 25 per cent after a few relapses, and most of the remainder have improved. It is probable that half of our members, had they not been drinkers, would have appeared in ordinary life to be normal people. The other half would have appeared as more or less pronounced neurotic.

Alcoholics Anonymous, or "AA," popularly so-called, has but one purpose—one objective only—"To help other alcoholics to recover from their illness."

Nothing is asked of the alcoholic approaching us save a desire on his part to get well. He subscribes to no membership requirements, no fees or dues, nor is a belief in any particular point of view, medical or religious, demanded of him. As a group we take no position on any controversial question. Emphatically, we are not evangelists or reformers. Being alcoholics who have recovered, we aim to help only those who want to get well. We do this because we have found that working with other alcoholics plays such a vital part in keeping us all sober.

You may inquire "Just how does AA work?" I cannot fully answer that question. Many AA techniques have been adopted after a ten-year process of trial and error which has led to some interesting results. But as laymen we doubt our own ability to explain them. We can only tell you what we do, and what seems, from our point of view, to happen to us.

At the very outset we should like it made ever so clear that AA is a synthetic concept—a synthetic gadget, as it were, drawing upon the resources of medicine, psychiatry, religion, and our own experience of drinking and recovery. You will search in vain for a single new fundamental. We have merely streamlined old and proved principles of psychiatry and religion into such forms that the alcoholic will accept them. And then we have created a society of his own

kind where he can enthusiastically put these very principles to work on himself and other sufferers.

Then, too, we have tried hard to capitalize our one great natural advantage. That advantage is, of course, our personal experience as drinkers who have recovered. How often the doctors and clergymen throw up their hands when, after exhaustive treatment or exhortation, the alcoholic still insists, "But you don't understand me. You never did any serious drinking yourself, so how can you? Neither can you show me many who have recovered."

Now, when one alcoholic who has got well talks to another who hasn't, such objections seldom arise, for the new man sees in a few minutes that he is talking to a kindred spirit, one who understands. Neither can the recovered AA member be deceived, for he knows every trick, every rationalization of the drinking game. So the usual barriers go down with a crash. Mutual confidence, that indispensable of all therapy, follows as surely as day does night. And if this absolutely necessary rapport is not forthcoming at once it is almost certain to develop when the new man has met other AA's. Someone will, as we say, "click with him."

As soon as that happens we have a good chance of selling our prospect those very essentials which you doctors have so long advocated, and the problem drinker finds our society a congenial place to work them out for himself and his fellow alcoholic. For the first time in years he thinks himself understood and he feels useful, uniquely useful, indeed, as he takes his own turn promoting the recovery of others. No matter what the outer world still thinks of him, he now knows that he can get well, for he stands in the midst of scores of cases worse than his own who have attained the goal. And there are other cases precisely like his own—a pressure of testimony which usually overwhelms him. If he doesn't succumb at once, he will almost surely do so later when barleycorn builds a still hotter fire under him, thus blocking off all his other carefully planned exits from dilemma. The speaker recalls seventy-five failures during the first three years of AA—people we utterly gave up. During the past seven years sixty-two of these people have returned to us, most of them now making good. They tell us they returned because they knew they would die or go mad if they didn't. Having tried everything else within their means and having exhausted their pet rationalizations, they came back and

Read by invitation at the Annual Meeting of the Medical Society of the State of New York, New York City, May 3, 1944.

\* One of the originators of Alcoholics Anonymous.

took their medicine. That is why we never need to evangelize alcoholics. If still in their right minds they come back, once they have been well exposed to AA.

Now to recapitulate. Alcoholics Anonymous has made two major contributions to the program of psychiatry and religion. These are, it seems to us, the long-missing links in the chain of recovery:

1. Our ability, as ex-drinkers, to secure the confidence of the new man—to "build a transmission line into him."
2. The provision of an understanding society of ex-drinkers in which the newcomer can successfully apply the principles of medicine and religion to himself and others.

So far as we AA's are concerned, these principles, now used by us every day, seem to be in surprising agreement. Let's compare briefly what in a general way medicine and religion tell the alcoholic:

#### Medicine Says

1. The alcoholic needs a personality change.
2. The patient ought to be analyzed and should make a full and honest mental catharsis.
3. Serious personality defects must be cured through accurate self-knowledge and realistic readjustment to life.
4. The alcoholic neurotic retreats from life, is a picture of anxiety and abnormal self concern; he withdraws from the "herd."
5. The alcoholic must find "a new compelling interest in life," must "get back into the herd." He should find an interesting occupation, should join clubs, social activities, political parties, or discover hobbies to take the place of alcohol.

#### Religion Says

1. The alcoholic needs a change of heart, a spiritual awakening.
2. The alcoholic should make examination of the "conscience" and a confession—or a moral inventory and a frank discussion.
3. Character defects (sins) can be eliminated by acquiring more honesty, humility, unselfishness, tolerance, generosity, love, etc.
4. The alcoholic's basic trouble is self-centeredness. Filled with fear and self-seeking, he has forgotten the brotherhood of man.
5. The alcoholic should learn the "expulsive power of a new affection," love of serving man, of serving God. He must "lose his life to find it"; he should join the church and there find self-forgetfulness in service. For "faith without works is dead."

Thus far, religion and medicine are seen in hearty accord. But in one respect they do differ. When the doctor has shown the alcoholic his underlying difficulties and has prescribed a program of readjustment, he says to him, "Now that you understand what is required for recovery,

you should no longer depend on me. You must depend upon yourself. *You go do it.*"

Clearly, then, the object of the doctor is to make the patient self-sufficient and largely, if not wholly, dependent upon himself.

Religion does not attempt this. It says that *faith in self is not enough*, even for a nonalcoholic. The clergyman says that we shall have to find and depend upon a higher power—God. He advises prayer and frankly recommends an attitude of unwavering reliance upon Him who presides over all. By this means we discover a strength much beyond our own resources.

So, the main difference seems to add up to this: Medicine says, "Know yourself, be strong, and you will be able to face life." Religion says, "Know thyself, ask God for power, and you become truly free."

In Alcoholics Anonymous the new man may try either method. He sometimes eliminates "the spiritual angle" from "Twelve Steps to Recovery" and wholly relies upon honesty, tolerance, and "working with others." But it is curious and interesting to note that faith always comes to those who try this simple approach *with an open mind*—and in the meantime they stay sober.

If, however, the spiritual content of the "Twelve Steps" is actively denied, they can seldom remain dry. That is our AA experience everywhere. We stress the spiritual simply because thousands of us have found we can't do without it.

At this point I should like to state the "Twelve Steps" of the Alcoholics Anonymous Program of Recovery so that you physicians may accurately compare your methods with ours.

#### The Twelve Steps

1. We admitted we were powerless over alcohol—that our lives had become unmanageable.
2. Came to believe that a power greater than ourselves could restore us to sanity.
3. Made a decision to turn our will and our lives over to the care of God as we understood him.
4. Made a searching and fearless moral inventory of ourselves.
5. Admitted to God, to ourselves, and to another human being the exact nature of our wrongs.
6. Were entirely ready to have God remove all these defects of character.
7. Humbly asked Him to remove our shortcomings.
8. Made a list of all persons we had harmed, and became willing to make amends to them all.
9. Made direct amends to such people wher-

ever possible, except when to do so would injure them or others

10 Continued to take personal inventory and when we were wrong promptly admitted it

11 Sought, through prayer and meditation, to improve our conscious contact with God as we understood Him, praying only for knowledge of His will for us and the power to carry that out

12 Having had a spiritual experience as the result of these steps, we tried to carry this message to alcoholics, and to practice these principles in all our affairs

Boiled down, these steps mean, simply (1) admission of alcoholism, (2) personality analysis and catharsis, (3) adjustment of personal relations, (4) dependence upon some higher power, and (5) working with other alcoholics

Most strongly we point out that adherence to these principles is not a condition of AA membership. Any alcoholic who admits he has a problem is an AA member regardless of how much he disagrees with the program. Based upon our experience, the whole program is a suggestion only. The alcoholic, objecting at first to the spiritual factor, is urged to keep an open mind, meanwhile treating his own AA group as "a power greater than himself." Under these conditions the newcomer commences to undergo a personality change at such a rate and of such dimensions that he cannot fully account for it on the basis of self-realization and self discipline. Not only does his alcoholic obsession disappear but he finds himself progressively free of fear, resentment, and inferiority. These changes seem to have come about almost automatically. Hence he concludes that "A power greater than himself" must indeed have been at work. Having come to this point, he begins to form his own concept of God. He then develops confidence in that concept, which grows as he gets proof in everyday life that his new faith actually works, really produces results.

This is what most AA's are trying to say when they talk about a spiritual experience. They mean a certain quality of personality change which, in their belief, could not have occurred without the help and presence of the creative spirit of the universe.

With the average AA many months may elapse before he is aware of faith in the spiritual sense. Yet I know scarcely an AA member of more than a year's standing who still thinks his transformation wholly a psychologic phenomenon based entirely upon his own normal resources. Almost everyone of our members will tell you that, while he may not go along with a clergyman's concept of God, he has developed one of his own on which he can positively depend—one which works for him.

We AA's are quite indifferent to what people may call this spiritual experience of ours. But to us it looks very much like conversion, the very thing most alcoholics have sworn they never would have. In fact I am beginning to believe that we shall have to call it just that, for I know our good friend, Dr. Harry Tiebout, is sitting here in this room. As you may know, he is the psychiatrist who recently told his own professional Society, The American Psychiatric Association, that what we AA's get is conversion—sure enough and no fooling! And if the spirit of that great psychologist, William James, could be consulted, he'd doubtless refer us to his famous book, *Varieties of Religious Experience* in which personality change through the "educational variety of spiritual experience, or conversion" is so ably explored. Whatever this mysterious process is, it certainly seems to work, and with us who are on the way to the asylum or the undertaker anything that works looks very, very good indeed.

And I'm very happy to say that many other distinguished members of your profession have pronounced our twelve steps good medicine. Clergymen of all denominations say they are good religion, and of course we AA's like them because they do work. Most ardently we hope that every physician here today will find himself able to share this happy agreement. In the early years of AA, it seemed to us alcoholics that we wandered in a sort of no-man's land which appeared to divide science and religion. But all that has changed since AA has now become a common meeting ground for both concepts.

Yes, Alcoholics Anonymous is a cooperative venture. All cases requiring physical treatment are referred to you physicians. We frequently work with the psychiatrist and often find that he can do and say things to a patient which we cannot. He, in turn, avails himself of the fact that as ex-alcoholics we can sometimes walk in where he fears to tread. Throughout the country we are in daily touch with hospitals and sanitariums, both public and private. The enthusiastic support given us by so many of your noted institutions is something for which we are deeply grateful. The opportunity to work with alcoholics means everything, to most of us it means life itself. Without the chance to forget our own troubles by helping others out of theirs, we would certainly perish. That is the heart of AA—it is our lifeblood.

We have torn still other pages from the Book of Medicine, putting them to practical use. It is from you gentlemen we learn that alcoholism is a complex malady, that abnormal drinking is but a symptom of personal maladjustment to life, that, as a class, we alcoholics are apt to be

sensitive, emotionally immature, grandiose in our demands upon ourselves and others; that we have usually "gone broke" on some dream ideal of perfection; that, failing to realize the dream, we sensitive folk escape cold reality by taking to the bottle; that this habit of escape finally turns into an obsession, or, as you gentlemen put it, a compulsion to drink so subtly powerful that no disaster, however great, even near death or insanity, can, in most cases, seem to break it; that we are the victims of the age-old alcoholic dilemma: our obsession guarantees that we shall go on drinking, but our increasing physical sensitivity guarantees that we shall go insane or die if we do.

When these facts, coming from the mouths of you gentlemen of science, are poured by an AA member into the person of another alcoholic they strike deep—the effect is shattering. That inflated ego, those elaborate rationalizations by which our neurotic friend has been trying to erect self-sufficiency on a foundation of inferiority, begin to ooze out of him. Sometimes his deflation is like the collapse of a toy balloon at the approach of a hot poker. But deflation is just what we AA's are looking for. It is our universal experience that unless we can start deflation, and so self-realization, we get nowhere at all. The more utterly we can smash the delusion that the alcoholic can get over alcoholism "on his own," or that someday he may be able to drink like a gentleman, the more successful we are bound to be.

In fact, we aim to produce a crisis, to cause him to "hit bottom," as AA's say. Of course you will understand that this is all done by indirection. We never pronounce sentences, nor do we tell any alcoholic what he *must* do. We don't even tell him he is an alcoholic. Relating the seriousness of our own cases, we leave him to draw his own conclusions. But once he has accepted the fact that he *is* an alcoholic and the further fact that he is powerless to recover unaided, the battle is half won. As the AA's have it, "he is hooked." He is caught as if in a psychological vise.

If the jaws of it do not grip him tightly enough at first, more drinking will almost invariably turn up the screw to the point where he will cry "Enough!" Then, as we say, he is "softened up." This reduces him to a state of complete dependence on whatever or whoever can stop his drinking. He is in exactly the same mental fix as the cancer patient who becomes dependent, abjectly dependent, if you will, on what you men of science can do for cancer. Better still, he becomes "sweetly reasonable," truly open-minded, as only the dying can.

Under these conditions, accepting the spiritual

implications of the AA program presents no difficulty even to the sophisticate. About half the AA members were once agnostics or athiests. This dispells the notion that we are only effective with the religiously susceptible. You remember the now famous remark, "There are no athiests in the foxholes." So it is with most alcoholics. Bring them within range of the AA and "block-busters" will soon land near enough to start radical changes in outlook, attitude, and personality.

These are some of the basic factors which perhaps partly account for such success as we have had. I wish time permitted me to give you an intimate glimpse of our life together, of our meetings, of our social side, of those fast friendships unlike any we had known before, of our participation by thousands in the war effort and the armed services, where so many AA's are discovering that they can face up to reality—no longer institutionalized, even within an AA Group. We have all found that God can be relied upon both in Alaska and India, that strength can come out of weakness, that perhaps only those who have tasted the fruits of reliance upon a higher power can fully understand the true meaning of personal liberty, freedom of the human spirit.

Surely, you who are here this morning must realize how much we AA's are beholden to you, how much we have borrowed from you, how much we still depend upon you. For you have supplied us ammunition which we have used as your lay assistants—gun pointers for your artillery. I have put out for inspection our version of the factors which bring about personality change, our method of analysis, catharsis, and adjustment. I have tried to show you a little of our great new compelling interest in life—this society where men and women understand each other, where the clamors of self are lost in our great common objective, where we can learn enough of patience, tolerance, honesty, humility, and service to subdue our former masters—insecurity, resentment, and unsatisfied dreams of power.

But I must not close without paying tribute to our partner, Religion. Like Medicine, it is indispensable. At this temple of science I hope none will take it amiss if I give Religion the last word:

"God grant us the serenity to accept the things we cannot change, courage to change the things we can, and wisdom to know the difference."

Please address inquiries and requests for AA literature to The Alcoholic Foundation, Box 459, Grand Central Annex, New York 17, New York.

## SAFE . . . CONVENIENT when mother and baby must travel

The mother has only to measure out and place in dry, sterile feeding bottles, the prescribed amount of Similac powder for each individual feeding. The bottles containing the measured Similac powder are then capped, and can be conveniently carried, along with a thermos bottle of boiled water cooled to about blood heat. At feeding time it is necessary only to pour into one of the bottles containing the measured Similac powder, the prescribed amount of water, then shake until the Similac is dissolved, place a nipple on the bottle, and feed.

A powdered, modified milk product especially prepared for infant feeding, made from tuberculin tested cow's milk (casein modified) from which part of the butter fat is removed and to which has been added lactose, olive oil, coconut oil, corn oil and fish liver oil concentrate.

## Discussion

**Dr. G. Kirby Collier, Rochester.**—Realizing how ineffectual our efforts in the treatment of the chronic alcoholic through the usually accepted psychiatric procedures were was my reason for investigating Alcoholics Anonymous. With one of their members I was privileged to attend a meeting in New York and had the opportunity of discussing their philosophy with Mr. Wilson. First, I was impressed with the honesty and sincerity of those members I met, and, second, with the broad socioreligious background and its psychiatric implications—chiefly man's recognition of self, his abilities as well as his inefficiencies, and that intangible power which all mankind recognizes, whether he acknowledges it or not. Upon my return home, I asked three chronic alcoholics, all of twenty to twenty-five years' duration, to organize as a group, after going over the situation with them as I understood it. These three contacted others and held their first meeting in the small apartment of one. Growing, they approached me as to a place for meeting. We eliminated the Y.M.C.A., Public Library, church halls, or parish houses for obvious reasons, and at last advised a room in one of our large centrally located hotels. This has worked out nicely and meetings are held each Sunday afternoon and Wednesday evening. From the original group of three, contacts have been made with over 500, of whom 60 per cent are active members, having been free from indulgence in alcohol for one to two years.

In our city we have had a Council on Alcohol for about three years. The group consists of psychiatrists, social workers, and others, who meet each month for discussion. At two of these meetings members of AA have spoken, and, as a result, two members of AA are now members of this Council. Members of AA are frequently called upon to address various groups, and it is most interesting to hear of men who have never spoken in public before being willing to get up and talk before any group. In Rochester they have become especially interested in meeting with youth groups. I might say that I have attended but few meetings of the Rochester group and these only at their invitation. I have felt that AA is a group unto themselves and their best results can be had under their own guidance, as a result of their philosophy. Any therapeutic or philosophic procedure which can prove a recovery rate of 50 to 60 per cent must merit our consideration. As stated by Tiebout in a paper read at Detroit, Michigan, before the American Psychiatric Association in May, 1943, "It is highly imperative for us, as presumably open-minded scientists, to view wisely and long the efforts of others in our field of work. We may be wearing bigger blinders than we know."

**Dr. Foster Kennedy, New York City.**—We have heard a truly moving and eloquent address, moving in its form and in its facts.

I have no doubt that a man who has cured himself of the lust for alcohol has a far greater power for curing alcoholism than has a doctor who has never been afflicted by the same curse. No matter

how sympathetic and patient the doctor may be in the approach to his patient, the patient is sure either to feel, or to imagine, condescension to himself, or to get the notion that he is being hectored by one of the minor prophets.

This organization of Alcoholics Anonymous calls on two of the greatest reservoirs of power known to man—religion and that instinct for association with one's fellows which Trotter has called the "herd instinct." Religious faith has been described by Matthew Arnold as a convinced belief in a power greater than ourselves that makes for righteousness, and a sense of helpfulness from this can be acquired through a kind of spiritual conversion which might well be called a variety of religious experience.

The sick man's association with those who, having been sick, have become or are becoming well, is a therapeutic suggestion of cure and an obliteration of his feeling of being, in society, a pariah; and this tapping of deep internal forces is shown by the great growth of this sturdy and beneficent movement. Furthermore, this movement furnishes an objective of high emotional driving power in making every cured drunkard a missionary to the sick.

We physicians, I think, have always had difficulty in finding an occupation for our convalescent patients of sufficient emotional driving power to replace the psychic results of the alcohol that has been withdrawn. These men grow filled with a holy zeal, and the very zealousness keeps the missionary steady while the next man is being cured.

I think our profession must take appreciative cognizance of this great therapeutic weapon. If we do not do so, we shall stand convicted of emotional sterility and of having lost the faith that moves mountains, without which medicine can do little.

**Dr. Harry M. Tiebout, Greenwich, Connecticut.**—My first contact with AA began five years ago when a patient with whom I had been working for well over a year came under the influence of AA and within a relatively short time dried up and for at least four years has remained completely dry. At that time I was puzzled and a little indignant that my best efforts had failed but AA had worked; but I kept sending patients, and now the situation has reversed. I get puzzled and a little indignant when AA doesn't work.

As a psychiatrist, I have had to think about the relationship of my specialty to AA and I have come to the conclusion that our particular function can very often lie in preparing the way for the patient to accept any sort of treatment or outside help. I now conceive the psychiatrist's job to be the task of breaking down the inner resistance so that which is inside will flower, as under the activity of the AA program.

In this respect I should like to point out that the same flowering can take place with patients who are not alcoholics, and I should like at this time to record my indebtedness to Mr. Wilson and AA for the understanding which has made by own therapeutic practice a more intelligent and meaningful process in so far as my own attitude is concerned. I now have more faith in the patient's own inner resources.

# Postgraduate Medical Education

*Programs arranged by the Council Committee on Public Health and Education of the Medical Society of the State of New York are published in this section of the JOURNAL. The members of the committee are Oliver W. H. Mitchell, M.D., Chairman (428 Greenwood Place, Syracuse); George Baehr, M.D., and Charles D. Post, M.D.*

## Teaching Day on Poliomyelitis in Buffalo

A TEACHING day on poliomyelitis was held in the Hotel Statler in Buffalo on August 3. The afternoon meeting, held at 4:00 P.M., was intended for the physicians of Region 12, comprising Cattaraugus, Chautauqua, Erie, Genesee, Niagara, and Wyoming counties. The meeting was called to order by Dr. John D. Naples, president of the Medical Society of the County of Erie. The chairman of the meeting was Dr. A. Wilmot Jacobsen, acting regional chairman in pediatrics.

"Clinical Features of Poliomyelitis—Pathology, Diagnosis, and General Treatment" was the title of the lecture given by Dr. James L. Wilson, professor of pediatrics and director of the department of pediatrics at New York University College of Medicine.

Following this lecture Dr. Kristian G. Hansson, assistant professor of clinical surgery (orthopaedics) at Cornell University Medical College, spoke on "Physical Therapy in the Acute and

Convalescent Stages." General discussion followed the lectures.

The evening meeting was public and also took place at the Hotel Statler, at 8:00 P.M. Dr. Frank N. Potts, professor and head of the department of orthopaedic surgery at the University of Buffalo School of Medicine, was chairman of the meeting. Dr. James E. Perkins, Director of the Division of Communicable Diseases of the State Department of Health, spoke on "Epidemiology of Poliomyelitis."

The program was presented under the auspices of the Woman's Auxiliary to the Medical Society of the County of Erie, the medical societies of the counties of Cattaraugus, Chautauqua, Erie, Genesee, Niagara, and Wyoming, the Medical Society of the State of New York, the New York State Department of Health, and the Buffalo and Erie County Chapter of the National Foundation for Infantile Paralysis.

## Madison County Society Hears "Penicillin Therapy"

A SINGLE lecture entitled "Penicillin Therapy" was given before the Madison County Medical Society on August 10 at 6:30 P.M., at the summer home of Dr. Howard Beach at Sylvan Beach, New York.

The speaker was Dr. Paul C. Clark, assistant

professor of clinical medicine at Syracuse University College of Medicine.

This instruction was presented as a joint endeavor of the Medical Society of the State of New York and the New York State Department of Health.

## Instruction in Tropical Diseases for St. Lawrence County

A LECTURE, "Tropical Medicine," will be given before the St. Lawrence County Medical Society on August 17, at 12:30 P.M., at the Gouverneur Country Club in Gouverneur.

Dr. O. D. Chapman, professor of bacteriology and parasitology at Syracuse University College of

Medicine, will speak and will illustrate his lecture with colored films.

This instruction will be presented as a cooperative endeavor between the Medical Society of the State of New York and the New York State Department of Health.

## ISONIPECAINE OR DEMEROL NOW SUBJECT TO NARCOTIC LAW

Effective July 1, 1944, Isonipecaïne or Demerol was made subject to the Federal Narcotic Laws, and all physicians desiring the right to prescribe or have this drug on hand must be registered in the appropriate class.

Physicians, etc., at present registered under the Harrison Narcotic Law will not be required to secure additional registration.

However, every sale or transfer of Demerol which is made subsequent to the effective date of the act will be required to be made pursuant to an official narcotic order form or physician's prescription in the

same manner and to the same extent as morphine.

Physicians who have had Demerol on hand since July 1, 1944, will be required to file with their local Collector of Internal Revenue on or before September 1, 1944, on Form 713 a supplementary inventory to the one filed at the beginning of the current fiscal period 1944-1945, showing all Demerol on hand as of July 1, 1944. Physicians requiring Form 713 may secure such forms at the office of the Collector of Internal Revenue where they are at present registered for a narcotic permit.

## Problem in Thyroid Therapy...

*same product...*

*same potency?*

Good results can be achieved only by use of a thyroid preparation which is carefully prepared and accurately standardized. Since thyroid substance is a potent drug, administration calls for careful adjustment of dosage, sometimes over long periods, to obtain the therapeutic action required to meet each patient's needs.

Burroughs Wellcome & Co. were pioneers in the development of thyroid preparations of constant, dependable potency. That is why "Tabloid" Thyroid products are relied upon and prescribed by physicians throughout the world.

## Amendments to State Sanitary Code and Recommendations of Advisory Group on Poliomyelitis

AT A MEETING held on June 7, the Advisory Group on Poliomyelitis to the New York State Department of Health and the New York City Department of Health carefully reviewed all available evidence and agreed unanimously to the following:

1. That all patients in whom a diagnosis of anterior poliomyelitis is suspected should be cared for in a hospital and that these patients may be safely admitted to the general wards but that it might be desirable to separate the patients in special wards for ease in handling.

2. That it be recommended to the Public Health Council of New York State and the Board of Health of New York City that quarantine procedures in hospitals be eliminated but that concurrent disinfection of all excretions be continued.

3. That all patients should be treated whenever possible under the combined supervision of the pediatrician, orthopaedic surgeon, and specialist in physical medicine, and that during the acute stage the patient should be kept at complete rest and disturbed as little as possible; that during the acute stage the therapeutic value of hot moist packs (or if not available, other methods of applying heat) is recognized as of great value for the general comfort of the patient in the elimination of pain and soreness where they occur, whether these occur at rest or on movement; that splints should not be used in the acute stage of the disease except in specific instances as determined by an orthopaedic surgeon.

4. A complete physical examination should be made to determine the residual muscle weakness or paralysis as soon as the patient's general condition permits and local muscle pain or soreness has subsided. If muscle weakness or paralysis is present, re-examination is indicated at intervals of one to two weeks depending upon the severity. If there is no impairment in muscle strength within two weeks after onset, gradual increase in the patient's activity may be permitted under careful supervision.

One month after discharge from the hospital the

absence of muscle weakness should be verified by re-examination. The after-care of patients with muscle weakness or paralysis should be determined after joint observation by the specialists concerned.

The Advisory Group includes the following members: Dr. Alan DeForest Smith, professor of orthopaedic surgery, College of Physicians and Surgeons, Columbia University; Dr. Philip Duncan Wilson, chief orthopaedist, Hospital of Special Surgery, New York City; Dr. William Benham Snow, associate professor of medicine, College of Physicians and Surgeons, Columbia University; Dr. James L. Wilson, professor of pediatrics, New York University; Dr. R. Plato Schwartz, associate professor of orthopaedic surgery, University of Rochester; Dr. Kristian G. Hansson, chief of physiotherapy, Hospital for Special Surgery, New York City.

The sulfonamide drugs have been remarkably effective in curing illness due to infection with meningococcus and in promptly eliminating the inciting micro-organism from the nose and throat secretions. Isolation of the patient after he has recovered and quarantine of household contacts have not

been shown to be of sufficient value in control of the disease to warrant the inconvenience to the patient and his family. Likewise, isolation of the patient after recovery and quarantine of the household contacts have been ineffective in the control of poliomyelitis, in which the epidemiology is similar.

Immediate isolation of every patient who presents evidence of acute illness, regardless of its nature and before as well as after diagnosis is made, would be of greater value in the prevention of spread of most communicable disease.

The Public Health Council, at its meeting on June 27, amended Chapter II, Regulations 15 and 17, of the Sanitary Code on the basis of the foregoing considerations. Essentially identical changes were made July 11 by the New York City Board of Health in the city Code.

Chapter II, Regulation 28, relating to the confi-

### National Farm Safety Week

By the President of the United States of America  
A Proclamation

WHEREAS, it behooves this Nation gratefully to acknowledge its special dependence upon the skill and labor of its farmers in the gigantic task of waging war; and

WHEREAS, the loss of life and limb by accident among our farming population has already reached an appalling figure, and the risks have lately been increased by longer hours of work and consequent fatigue; and

WHEREAS, it is essential to our war effort that this waste of vital farm power be minimized in every possible way:

Now, therefore, I, Franklin D. Roosevelt, President of the United States of America, do hereby call upon the Nation to observe the week commencing July 23, 1944, as National Farm Safety Week. And I request all persons and organizations concerned with agriculture and farm life to unite in an effort, during this National Farm Safety Week, to stimulate among farmers a full realization of the need for constant attention to the old and familiar precautions against the hazards of their calling, and also to awaken in them a sense of responsibility for the proper instruction in rules of safety of the many young and inexperienced persons now being employed on farms in all parts of the country.

In witness whereof, I have hereunto set my hand and caused the seal of the United States of America to be affixed.

Done at the City of Washington this sixteenth day of June, in the year of our Lord nineteen hundred and forty-four, and of the Independence of the United States of America the one hundred and sixty-eighth.

(Signed) FRANKLIN D. ROOSEVELT

By the President:

(Signed) CORDELL HULL, Secretary of State

# SOPRONOL *Inhibits* FUNGOUS INFECTIONS

MONILIA  
albicans

EPIDERMOPHYTON  
inguinale

MICROSPORUM  
audouinii

TRICHOPHYTON  
purpureum

... As demonstrated by clinical investigation  
in a leading United States hospital

In tests on a large number of hospital patients, Sopronol was found to exert an *inhibitory* rather than a destructive action on the fungus. The advantages of this method are obvious. Sopronol, taken readily into the fungous organism, prevents its development and spread. Hence the infection is quickly brought to an end, but without the customary skin irritation caused by poisonous by-products resulting from strong fungicides in contact with the mold. The chemical basis of Sopronol is sodium propionate.

## ALL SUPERFICIAL MYCOSES (RINGWORM)

Prescribe Sopronol for: Tinea Pedis, Tinea Cruris, Tinea Capitis, Tinea Glabrosa, due to "the dermatophytes"—Trichophyton, Epidermophyton, Microsporum, Monilia (Candida) and pathogenic aspergillae infections. Sopronol is non-irritating, non-keratolytic, non-toxic.

Available in alcoholic solution, powder  
and water soluble ointment bases

MYCOLOID LABORATORIES, INC., Little Falls, New Jersey

Please send me descriptive literature and reprints as checked:

dential nature of tuberculosis reports, was also amended.

The amended regulations, effective July 15, 1944, are reproduced below.

## CHAPTER II

### Communicable Diseases

Regulation 15. Persons suffering from chickenpox, bacillary dysentery, measles,\* *meningococcus meningitis* or *meningococcemia* (septicemia), ophthalmia neonatorum, pneumonia, poliomyelitis, epidemic or streptococcus (septic) sore throat, typhoid and paratyphoid fever to be isolated. Whenever a case of one of the diseases mentioned in this regulation comes to the attention of the health officer, he shall establish and maintain isolation of such case for the period specified herein; when isolation on the premises is impracticable, the health officer may cause the removal of the patient to a suitable hospital.

Chickenpox: until recovery.

Measles: until recovery.

*Meningococcus meningitis* or *meningococcemia* (septicemia): until end of the febrile stage.

Ophthalmia neonatorum: until two successive specimens of the discharges obtained from each eye, taken at intervals of not less than forty-eight hours, shall have been found free from gonococci or other causative micro-organisms in an approved laboratory.

Pneumonia: until recovery.

Poliomyelitis: until end of the febrile stage.

Epidemic or streptococcus (septic) sore throat: until recovery.

Typhoid fever: for ten days after clinical recovery from the disease. After the termination of such period of isolation such patient shall conform to the regulations for the control of typhoid carriers until two successive specimens of feces passed not less than three weeks after the date of onset and at an interval of not less than five days shall have been examined in an approved laboratory and found to be free from typhoid bacilli; a person who has recovered from typhoid fever shall not engage in the handling of milk, dairy products, or other foods until all secondary or complicating infections incited by the agents of this disease have disappeared and until four successive specimens of the intestinal discharges and urine of the person passed not less than three weeks after the date of onset and at intervals of not less than five days have been examined in an approved laboratory and found to be free from typhoid bacilli; provided that any person in whose feces or urine typhoid bacilli are present one year after such person has recovered from typhoid fever shall be released from the restrictions for typhoid carriers only with the approval of the state commissioner of health.

Paratyphoid fever: for five days after clinical recovery from the disease, except that no person shall engage in the handling of milk, dairy products, or other foods until clinical recovery and until four successive specimens of intestinal discharges and urine, passed not less than one week after the date of onset and at intervals of not less than five days shall have been examined in an approved laboratory and no paratyphoid bacilli shall have been found.

Bacillary dysentery: for five days after clinical recovery from the disease, except that no person shall engage in the handling of milk, dairy products, or other foods until clinical recovery and until four successive specimens of intestinal discharges passed not less than one week after the date of onset and at intervals of not less than twenty-four hours shall have been examined in an approved laboratory and found to be free from organisms of the dysentery group.

This amendment shall take effect July 15, 1944.

Regulation 17. Diphtheria, [meningococcus meningitis or meningococcemia (septicemia), poliomyelitis] and scarlet fever. Isolation of case, quarantine of children of household, and modified quarantine for adult household contacts.

\* Matter in italics is new; matter in brackets is deleted.

Whenever a case of one of the diseases mentioned in this regulation shall come to the attention of the health officer, he shall isolate the patient and establish and maintain quarantine for the periods hereinafter stated, provided, however, [that adult household contacts to a case of poliomyelitis, meningococcus meningitis, or meningococcemia (septicemia), shall not be quarantined and] that if a case of diphtheria or scarlet fever is properly isolated on the premises, quarantine shall be so modified as to permit adult household contacts who show no evidence of infection and will not be subsequently exposed to the patient or his secretions or excretions to follow any vocation which does not involve the handling of food or close association with children. When isolation on the premises is impracticable, the health officer may cause the removal of the patient to a suitable hospital.

Diphtheria: isolation until two successive cultures taken from the nose and throat at intervals of not less than twenty-four hours have been found free from diphtheria bacilli in an approved laboratory, the first of such cultures being taken not less than one week from the day of the onset of the disease; except that if diphtheria bacilli continue to be present in cultures after five weeks from the date of taking the first release culture, the health officer, in his discretion, may declare the person to be a diphtheria carrier.

Personal quarantine of household contacts, except as otherwise provided herein, until cultures taken from both nose and throat subsequent to last exposure have been found free from diphtheria bacilli in an approved laboratory.

Quarantine of premises: until release of patient and household contacts.

[Meningococcus meningitis or meningococcemia (septicemia): isolation until two weeks after the temperature has become normal.]

[Personal quarantine of children of household until release of patient.]

[Poliomyelitis: isolation until fourteen days after the day of the onset of the disease.]

[Personal quarantine of children of household until release of the patient.]

Scarlet fever: isolation until twenty-one days after the development of the disease and until all discharges from the nose, throat, and ears, and suppurating glands have ceased, provided that such isolation shall not continue for more than ninety days.

Personal quarantine of household contacts, except as otherwise provided herein, until the release of the patient, provided that if such contact does not continue to reside on the same premises as the patient, quarantine shall continue until one week after last exposure.

This amendment shall take effect July 15, 1944.

Regulation 28. [Records] Reports of tuberculosis cases confidential. [Records of the state department of health, or of any local department of health or local health officer having custody of such records, or of any laboratory, clinic, or other institution relating to cases of tuberculosis, shall be confidential, except that access to such records by representatives of official public agencies or nonofficial agencies concerned with the control of tuberculosis may be permitted at the discretion of the state or local health officer having custody of such records. A statement as to the existence of tuberculosis in an individual may be made to an agency as above indicated by a state health officer or local health officer having custody of tuberculosis case records.] A state or local health officer authorized by law to receive laboratory or other reports relating to cases of tuberculosis may disclose information contained in such reports only when in his judgment [such disclosure] it will serve the best interest of the patient or his family, or contribute to the protection of the public health. Such officer may, subject to the foregoing purposes, permit access to such reports by representatives of official or nonofficial agencies concerned with the control of tuberculosis. [An official or other person to whom such information is furnished or to whom access to such records has been given shall not disclose such information except in so far as is necessary to serve the best interest of the patient or his family, or contribute to the protection of the public health.]

This amendment shall take effect July 15, 1944.—Reprinted from Health News, July 17, 1944

## New York Academy of Medicine to Hold Graduate Fortnight in October

THE seventeenth Graduate Fortnight of the New York Academy of Medicine will be held in New York City, October 9-20. The subject will be "Infections and Their Treatment." The program will consist of morning panel discussions, afternoon hospital clinics, evening addresses, and scientific exhibits and demonstrations.

Except for men in uniform, admission will be by registration card only. Fellows of the Academy will

be furnished registration cards without application. Others will receive cards after sending a check for five dollars, payable to the New York Academy of Medicine, to 2 East 103rd Street, New York 29, New York.

The officers of the Academy who are responsible for the Fortnight are: Arthur Freeborn Chace, president; Herbert B. Wilcox, director; The Com-

[Continued on page 1818]

## INDEFINITE GASTRIC DISCOMFORT

Symptoms of indefinite gastric discomfort frequently indicate hepatobiliary dysfunction. These complaints of flatulence, eructation, dyspepsia and post-prandial distress due to gall-bladder involvement, respond favorably to

# SORPARIN

A highly effective drug which stimulates the function of the liver cells, Sorparin is physiologically and mechanically safe and has no known contraindications. Large doses of Sorparin have been given with notable freedom from toxicity. Because it is nonkinetic, it may be used with confidence even in obstructive jaundice.

Sorparin does not depend on the presence of bile for absorption and utilization, and may be given in conjunction with sedatives, hydrochloric acid and antispasmodics. A rapid rise in plasma prothrombin results from its administration, due to its vitamin K-like activity. J. Lab. and Clin. Med. 27: 897-907, April 1942.

*Available in tablets, each containing 3 gr. Sorparin. Bottles of 100, 500 and 1000.*

**McNeil Laboratories**

mittee on Medical Education: Bernard S. Oppenheimer, *chairman*; the Graduate Fortnight Committee: Ralph H. Boots, *chairman*, Mahlon Ashford, *secretary*, George F. Cahill, Ralph Colp, Ross Golden, Franklin M. Hanger, Harrison S. Martland, Rustin McIntosh, R. Townley Paton, Robert E. Pound, and Charles F. Tenney; Committee on Hospital Clinics: R. Townley Paton, *chairman*, Hattie E. Alexander, Charles H. Nammack, J. M. Lewis, Thomas H. McGavack, Frederic D. Zeman, Louis Berger, Clarence E. de la Chapelle, Louis Leiter, George E. Milani, Reuben Ottenberg, Walsh McDermott, Edward Kellogg, Henry H. Ritter, Franklin M. Hanger, Frederick H. Amendola, Joseph Hajek, Jerome L. Kahn, and Albert H. Aldridge; Committee on scientific exhibit: Robert E. Pound, *chairman*, Courtenay I. Headland, Asa Liggett Lincoln, and Margaret Stanley-Brown; Committee on panel discussions: Charles F. Tenney, *chairman*, David P. Barr, Russell L. Cecil, Samuel J. Kopetzky, and Joseph Earle Moore.

Questions for the morning panel discussions should be sent in advance to Dr. Mahlon Ashford at the Academy or in writing to the chairman during the discussion.

The first discussion will be held Tuesday, October 10, 11:00-12:30 A.M., on the subject, "Pneumonia Types and Their Response to Various Forms of Chemotherapy." Dr. Russell L. Cecil will be chairman, and the members will be Dr. Alvan L. Barach, Dr. Maxwell Finland, of Boston, and Maj. Norman Plummer, (MC), AUS. On Friday, October 13, 11:00-12:30 A.M., the subject will be "Treatment of Syphilis and Gonorrhea." Dr. Joseph Earle Moore, of Baltimore, will be chairman, and the members will be Dr. Oscar F. Cox, of Boston, Dr. Harry Eagle, of Baltimore, and Dr. Evan W. Thomas. On Tuesday, October 17, 11:00-12:30 A.M., the subject will be "Treatment of Infections of the Eye, Ear, and Upper Respiratory Tract." Dr. Samuel J. Kopetzky will be the chairman, and the members will be Dr. Conrad Berens, Dr. C. Ward Crampton, Dr. W. Morgan Hartshorn, Dr. Wesley M. Hunt, Dr. Charles J. Imperatori, Dr. John D. Kernan, and Dr. Andrew B. Paul.

The afternoon hospital clinics will be held at Bellevue and Beth Israel on Tuesday, October 10; at Babies Hospital and Montefiore on Wednesday, October 11; at Morrisania and Mt. Sinai on Thursday, October 12; at the Home for Aged and Infirm Hebrews and Post-Graduate on Friday, October 13; at Lenox Hill and Woman's Hospital on Monday, October 16; at St. Luke's and Willard Parker on Tuesday, October 17; at Jewish Hospital of Brooklyn and Presbyterian on October 18; at Flower-Fifth

Avenue and New York on October 19; and at Polyclinic and Roosevelt on October 20.

The evening sessions will be held at the Academy at 8:30 P.M. On October 9 Dr. Arthur Freeborn Chace will deliver the address of welcome. Following this Dr. René J. Dubos will deliver the Ludwig Kast Lecture—in memory of Dr. Ludwig Kast, who proposed the Graduate Fortnight—entitled "The Mode of Action of Antibacterial Agents." Dr. Colin MacLeod will speak on "Factors Which Influence the Choice of Antibacterial Agents." On Tuesday, October 10, Brig. Gen. Hugh H. Morgan, USA, will speak on "Sulfonamides in the Control of Streptococcus Infections and Comdr. Alvin F. Coburn, MC-(S), USNR, will discuss "Mass Sulfadiazine Prophylaxis of Respiratory Diseases in the U.S. Navy."

On October 11 Dr. Francis G. Blake will discuss "Rickettsial Infections in the Southwest Pacific Area" and Brig. Gen. S. Bayne-Jones, USA, will give a lecture, "Infectious Hepatitis." On October 12 Dr. Joseph Earle Moore will speak on "Chemotherapy of Syphilis" and Dr. John F. Mahoney will speak on "Chemotherapy of Gonorrhea." On October 13 Dr. Russell L. Cecil will discuss "Chemotherapy in Acute Upper Respiratory Infections." Dr. Thomas Francis, Jr., will deliver the Carpenter Lecture—in memory of Dr. Wesley M. Carpenter—on the subject, "Influenza—Methods of Study and Control." On October 16 the first lecture will be "The Use of Penicillin in the Treatment of Pneumococcal Infections," by Dr. William S. Tillett, and the second will be "Primary Atypical Pneumonia," by Dr. John H. Dingle.

On October 17 Dr. J. Albert Key will speak on "Treatment of Poliomyelitis," Capt. Lewis K. Ferguson, (MC), USNR, will speak on "Treatment of Burns and War Wounds," and Dr. Philip D. Wilson will lead the discussion. On October 18 Dr. Harrison F. Flippin will discuss "Recent Developments in Sulfonamide Therapy" and Dr. Charles F. Janeway will speak on "Use of the Immune Globulin Fraction of Human Plasma in Acute Infections." On October 19 Dr. Wiley D. Forbus will give a lecture entitled "The Reactions of Tissues Following Infection and Their Place in an Environmental Conception of the Nature of Diseases." Lt. Comdr. Harold J. Harris, (MC), USNR, will speak on "Brucellosis (Undulant Fever)—Problems of Diagnosis and Treatment."

On October 20 a panel discussion on "The Evaluation of Sulfu Drugs and Penicillin" will be led by the chairman, Dr. David P. Barr. The members will be Dr. René J. Dubos, Dr. Colin MacLeod, Dr. John F. Mahoney, Dr. Frank L. Melaney, and Dr. William S. Tillett.

## Postwar Training of Medical Corps Officers

THE Office of the Surgeon General has announced the appointment of a committee to formulate plans for postwar training of Medical Corps officers who will be separated from the military service at the end of the war. The committee consists of Brig. Gen. Raymond W. Bliss, Chief of Operations Service, *Chairman*; Brig. Gen. James S. Simmons, Chief of Preventive Medicine Service; Col. James R. Hudnall, Chief of Personnel Service; Brig. Gen. Fred W. Rankin, Director of Surgery Division;

Brig. Gen. Hugh J. Morgan, Director of Medicine Division; Col. Floyd L. Wergeland, Director of Training Division; Col. William P. Holbrook, MC, and Lt. Col. R. H. Meiling, M.C., representatives from the Army Air Forces; Col. R. B. Skinner, MC, representative from the Army Ground Forces; George B. Darling, M.D., representative from the National Research Council.—*Release from the Office of the Surgeon General, July 22, 1944*

[Continued on page 1820]

THE SCIENCE OF ELECTRONICS ALSO PROVIDES A NEW TRIUMPH  
IN ELECTRO-MEDICAL ANALYSIS . . .

*New*

## EPL Direct-recording Electrocardiograph\* ... giving instantaneous standard readings

- An inkless, direct writing recorder, designed and developed by the Electro-Physical Laboratories, Inc., after years of research and experimentation
- Completely eliminates all photographic procedures
- The cardiograph record appears instantaneously for interpretation at the bedside
- Ease of operation and simplicity of control assure good records with minimum effort
- Compact, light, portable; simple to handle
- Readings exactly resemble those of the best string type galvanometers
- Electrical interference does not affect record
- Because the record is immediately observable, a new field for cardiography in surgical procedure and pharmacological research becomes possible
- Operates from any 110-120 volt, 60 cycle, AC service
- High operating economy

FIGURE A—Photographic Method

FIGURE B—EPL Method

FIGURE C—Calibration

The exact similarity between the standard photographic cardiogram and the direct instantaneous cardiogram on this new EPL instrument is indicated in Figures A and B, which are records of the same subject taken a few minutes apart.

**NOTE:** It has been determined by a series of measurements that cardiograms made on this instrument have no clinically detectable deviations from those made with the use of a high speed inertia less cathode ray oscilloscope.

AT PRESENT, DELIVERIES ON PRIORITY ONLY. WRITE FOR DESCRIPTIVE BROCHURE.

## Columbia Announces Postgraduate Courses in Clinical Medicine in October

THE faculty of medicine of Columbia University will conduct postgraduate courses in clinical medicine at Mount Sinai Hospital, New York City. The first semester will begin the week of October 2.

Part-time courses will be given in allergy, anesthesia, cardiovascular diseases, chemistry, advanced diseases of the chest, diagnosis and therapy, advanced electrocardiography, fluoroscopy and x-ray of the heart, gastroenterology, gastroscopy, elementary hematology, diseases of the kidneys and arteries, diseases of the liver and biliary passages, advanced clinical neurology, neuroanatomy, neuropathology, electroencephalography, embryology of the eye, external diseases of the eye, extraocular muscles, histopathology of the eye, ophthalmic neurology, ophthalmic surgery, elementary ophthalmology, physiologic optics, refraction, slit lamp microscopy, orthopaedics, otology, pediatrics, pharmacology, physical therapy, physiology of the gastro-intestinal tract, medical proctology, surgical proctology, and tropical medicine.

The courses in histopathology of the eye, ophthalmic surgery, and elementary ophthalmology will begin in September. The courses in neuroanatomy and neuropathology can be taken as full-time courses.

A full-time course, "Recent Advances in Gynecology," will be given November 13-18.

Applications should be submitted before September 15. For further information address the Secretary for Medical Instruction, The Mount Sinai Hospital, Fifth Avenue at 100th Street, New York 29, New York.

## Symposium on Fluorine and Dental Caries

THE first open meeting of the New York Institute of Clinical Oral Pathology will be held in Hosack Hall, the New York Academy of Medicine, on the evening of October 30. Speakers whose names will be announced later will participate in a symposium on "Fluorine and Dental Caries."

Members of the medical, dental, public health, and other professional groups are invited to attend. Further information may be obtained from the executive secretary of the New York Institute of Clinical Oral Pathology, 101 East 79th Street, New York 21, New York.

## County News

### Clinton County

The county society held a dinner meeting on July 3 at 6:30 p.m. at the Hotel Witherill in Plattsburg.

Dr. L. Whittington Gorham, of Albany Medical College, addressed the meeting on penicillin therapy.\*

### Erie County

Governor Dewey has appointed Alfred H. Kirchofer, managing editor of the Buffalo *Evening News*, and five physicians to the board of visitors to the State Institute for the Study of Malignant Diseases in Buffalo.

The physicians are Dr. George W. Cottis, Jamestown, past president of the State Medical Society; Dr. Walter L. Machemer, chief of the surgical department of Buffalo Children's Hospital; Dr. John J. Morton, chief surgeon of Strong Memorial Hospital, Rochester; Dr. James B. Murphy, New York City, a member of Rockefeller Institute; and Dr. Frederick S. Wetherell, surgeon of Memorial and St. Joseph's Hospitals, Syracuse.\*

### Oneida County

Dr. Herbert H. Bauckus, of Buffalo, president of the New York State Medical Society, addressed the Oneida County Medical Society at its monthly meeting in Utica on July 11. His subject was "The Coming Medical Era."

Dr. Bauckus is the first president of the Western New York Medical Plan, and past chairman of the Economics Committee of the State Society.

Investigation by the Red Cross of nonrecurring medical emergency cases in families of soldiers of the rank of corporal or less, and assistance for cases proved to be without any other help was explained.

The new plan of cooperation between the Utica Chapter of the Red Cross and the county society for the benefit of needy cases was presented by Dr. A. R. Hatfield, Jr.

Dr. P. L. Turner gave a report for the penicillin committee.

Dr. F. M. Miller, Jr., president, presided at the meeting, which opened at 7:00 p.m. with a dinner session.\*

### Orange County

The following hospitals in Orange County have been designated by the War Production Board as depots for penicillin distribution: St. Luke's Hospital at Newburgh; Horton Hospital at Middletown; St. Francis Hospital at Port Jervis.

The Horton Memorial Hospital at Middletown is now associated with Hartwick College at Oneonta as a Cadet Training School for nurses. The two other hospitals associated with Horton Hospital in the practical training of the enrolled cadet nurses are the Fox Memorial at Oneonta and the Murphy Memorial at Rome, New York. The Cadet Training School is headed by Miss Mary Murphy, Director of Education.

### Queens County

The date of the stated meeting of the county society has been changed from Tue day, September 26, to Thursday, September 28, at 9:00 p.m.

The Medical Society of the County of Queens, Inc., proposes to offer its members a course of lectures in industrial medicine. The program will

● Surbyl is a balanced combination of Sulfanilamide, Urea and Benzyl Alcohol in a Propylene Glycol base.

Surbyl has been found valuable in the treatment of otitis media, paronychia, varicose ulcers, infections of the hand or foot and as a dressing for wounds and abscesses.

Surbyl Solution is free from excess alkalinity. The pH is between 7.5 and 8.0 which is a desirable range for topical administration.

Available in pint and gallon quantities. Write for professional folder S-12.

*R. J. STRASENBURGH Co.*

PHARMACEUTICAL CHEMISTS SINCE 1866

ROCHESTER, NEW YORK

[Continued from page 1820]

be initiated at the regular stated meeting of the society on October 31.

The opportunities in industrial health will be discussed by Dr. Townsend, of the U.S. Public Health Service, from that viewpoint, and by Dr. Sawyer, of the Eastman Kodak Company, for the industrial physician. Thereafter, sessions will be held each Monday and Thursday (holidays excluded) until the ten contemplated meetings have been completed.

The problems to be discussed are:

1. Organization and administration of industrial medical department.
2. Compensation and welfare insurance.
3. Plant survey.
4. Occupational diseases—*pneumoconioses*.
5. Occupational diseases—*dermatoses*.
6. Diseases caused by toxic materials: (a) gases, (b) metals.
7. Environmental control of occupational hazards.
8. Medical and surgical specialties: (a) laboratory, (b) psychiatric, (c) orthopaedic, (d) eye.
9. Related professional specialties: (a) dental, (b) nursing, (c) personnel.
10. Special problems as related to: (a) nutrition, (b) absenteeism, (c) records, (d) rehabilitation.

To those whose attendance warrants, a certificate will be issued, stating that they have completed the course given by the Medical Society of the County of Queens, Inc.

#### St. Lawrence County

Dr. Roscoe D. Severance, associate professor of orthopaedic surgery, Syracuse University College of Medicine, discussed common orthopaedic defects at a meeting of the county society held at 1:00 P.M., July 13, at Massena Country Club.\*

Still active in his profession after more than fifty-five years of continuous practice, Dr. Hiram M. Buchanan, of Watertown, one of the oldest physicians in Jefferson County, both in point of age and years of practice, was 79 years old on June 29.

The doctor, enjoying good health, observed his birthday by performing his usual duties.\*

#### Schenectady County

More than 250 patients and friends from Schenectady and Schoharie counties attended a farewell surprise party for Dr. Donald C. Walker at Red Men's Lodge, Esperance, before he left for Sampson Naval Center. Dr. Walker has received a commission as a lieutenant in the Medical Corps.

A purse was presented to Lieutenant Walker, the local Red Cross gave him its forty-fifth sweater, and Mrs. Walker was given a bouquet. The presentations were made by District Attorney James L. Gage, of Schoharie County.\*

#### Suffolk County

Mass x-raying became the order of the day in Babylon Town recently when 3,658 residents, or approximately one-seventh of the total population of the area, received chest x-ray examinations.

It was the first town-wide program of its kind in Suffolk County and was jointly sponsored by the Suffolk County Tuberculosis and Public Health Association, the Suffolk County Health Department, and Suffolk Sanatorium. The activity was designed to promote the current program of tuberculosis control through the cooperative efforts of private physicians, official and nonofficial agencies, and community leaders.

# HYPERTENSION CASUALTIES

## ... Cardiac Failure

Essential hypertension regularly results in concentric hypertrophy of the left ventricle. If the hypertension persists, the hypertrophied heart eventually dilates and fails.

To aid the reduction of blood pressure quickly *without shock*—and maintain the reduction—physicians prescribe Natrico Pulvoids. This synergistic combination of vasodilators obtains full action of the nitrites, but avoids the disadvantages of the constituents when used alone.

### SYMPTOMATOLOGY

Natrico Pulvoids are especially useful in the symptomatic treatment of essential hypertension and for relief of *cardiac pain, headache, dizziness and tinnitus* due to arterial hypertension. Each Pulvoid contains. Potassium Nitrate, 2 grs, Sodium Nitrite 1 gr, Po. Ext. Crataegus Oxyacantha  $\frac{1}{4}$  gr, Nitroglycerin 1/250 gr. Supplied: Bottles of 100 Pulvoids

# N A T R I C O

## P U L V O I D S

Rx

# Pediforme

## FOOTWEAR

## for FLAT-FEET

The family physician, in health examinations, will not over-look examining the feet of babies and growing children for evidence of flat-feet through heredity tendencies or other causes—and will naturally prescribe measures for correction.

Proper shoes are essential to supplement the doctor's own treatments—but a proper source of supply is essential, too, and the patient of any age-group should be directed to competent and trustworthy fitters of correctly designed shoes of scientific construction. Pediforme footwear have the qualities desired by the doctor and the attractiveness so vital to the sensitive patient.

# Hospital News

## Penicillin Provided Free to Hospital Service Members

**PENICILLIN** will hereafter be provided, when necessary, without charge to the hospitalized members of Associated Hospital Service using semi-private and ward accommodations in two hundred and sixty hospitals of the New York area, according to an announcement by Louis H. Pink, president.

A special reserve fund is to be set up to reimburse hospitals for additional costs because of the use of

this and other unusual remedies required for the treatment of Associated Hospital Service members.

Mr. Pink said: "The board of directors believes that the Associated Hospital Service, in addition to budgeting normal hospital expense for its members, should help them take advantage of new developments in medicine whenever possible. . . . If other new and unusual drugs or services become available, their cost . . . will be met in the same manner."

## Hospital Superintendents Meet in Schenectady

**R**ECENT developments and current practice in the treatment of tuberculosis were discussed at the annual meeting of the State Tuberculosis Hospital Superintendents' Association at Glenridge Sanatorium in Schenectady on June 30.

Among those present at the meeting were Dr. James M. Blake, superintendent of Glenridge and past president of the association; Dr. Robert E. Plunkett, retiring secretary of the association, and members of the Glenridge board of managers, Laurence G. Magner, James A. Westlin, Dr. E. M. Stanton, and Howard White.

Dr. Fred C. Holcomb, of Kingston, was elected president, succeeding Dr. Blake, while Dr. Blake was elected secretary-treasurer of the organization. The next meeting of the group will be held in Kingston at the Ulster County Tuberculosis Hospital.

Dr. E. M. Medlar, of Bellevue Hospital, New York, and Dr. C. M. Graham, of Biggs Memorial Hospital, Ithaca, led a discussion on the use of diazone, a drug given wide publicity on the basis of being a cure

for tuberculosis. Both men stated that any credit given the drug had to be properly evaluated, and that, on the basis of current work, premature publicity had been given the treatment. The use of diazone, they stated, was still in the experimental stage, and, while the medical profession was still in search of a form of chemotherapy, diazone did not seem to be the answer.

Dr. B. L. Vosburgh, director of the General Electric Hospital, described the cooperation between the company and Glenridge in finding cases of tuberculosis principally by means of pre-employment x-rays.

The technical part of the meeting was completed with a discussion of thoracic surgery by Dr. A. M. Skinner, of Oneonta. A recommendation for the use of chest x-rays as part of general hospital procedure was made.

Dr. H. P. Groesbeck, president of the Glenridge board of managers, welcomed the superintendents to Schenectady.

## Improvements

Fully equipped to provide the biochemical requirements for further exploration of children's diseases, on June 30 the new research laboratory of Buffalo's Children's Hospital was opened for inspection to members of the hospital board, the University of Buffalo Medical School, physicians, and nurses.

The laboratory, which will be under direct supervision of Dr. Edward M. Bridge, research professor of pediatrics at the University of Buffalo, has some of the more recently developed scientific apparatus with which it hopes to supply the general chemical needs of the hospital.

There is a new unit for the study of epilepsy in its early stages, which includes the electro-encephalograph, a device capable of detecting certain brain

disturbances frequently responsible for epileptic conditions. Another phase of the laboratory's work will be carried on with the benefit of a metabolism chamber to study irregularities springing from sugar metabolism in children and especially in premature babies. At a later date, Dr. Bridge hopes to carry on laboratory research in kidney diseases relative to blood proteins and immunity.

Health Commissioner Francis E. Fronczak, who attended the opening of the laboratory, said "This sort of research should be carried on in every hospital. It is a fine laboratory and it should contribute heavily to the benefit of the public health."

The laboratory is a gift of the late E. M. Statler, hotel executive, and was made possible through the Statler Trust.\*

## At the Helm

Alfred Renshaw and Ellis Auer were elected members of the board of directors of the Associated Hospital Service of the State Capital District at the board's recent meeting.

Mr. Renshaw, president of the board of trustees of Albany Hospital, was elected to the vacancy caused

by the absence of Everett R. Jones. Mr. Auer, of Schenectady, replaces the late John Barry.\*

. . . .

Dr. Everett A. Jacobs, former Hudson physician, has been appointed head of the x-ray department at

# Woman's Auxiliary

## To the Medical Society of the State of New York

### County News

**Broome County.** The annual meeting of the Broome County Woman's Auxiliary was a luncheon meeting at the American Legion Clubhouse in Johnson City.

The table was decorated with a centerpiece of rambler roses and blue delphinium beautifully arranged by Mrs. Maxwell Snider. Mrs. R. T. Allen was the hospitality chairman and Mrs. William Low was in charge of the program, which included annual reports of all the committees.

The officers for the coming year were elected at this meeting. They are as follows: president, Mrs. M. M. Monserrate, re-elected; vice-president, Mrs. Harry Levy; secretary, Mrs. C. M. Allaben; corresponding secretary, Mrs. W. A. Ackroyd; treasurer, Mrs. R. M. Vincent. Directors are Mrs. M. W. Welch, Mrs. G. R. Cheatham, and Mrs. W. J. Farrell.

**Columbia County.** A strawberry festival, held in the Central House, marked the June meeting of the Columbia County Auxiliary, with Mrs. H. G. Henry presiding. After the usual business meeting Mrs. H. J. Noerling reported on the State Auxiliary Convention which was held in New York City. Mrs. Charles Briwa, of North Claverack, was announced the county commander of the Woman's Field Army for the Control of Cancer. The hearty support and cooperation of the auxiliary was requested for her in her work. The auxiliary is expecting to have a booth at the Chatham Fair in the Health Building. The auxiliary received high praise for their work and cooperation by Dr. C. L. Schultz, president of the county medical society.

**Herkimer County.** Officers of the Herkimer County auxiliary were elected at a meeting at the home of Mrs. F. C. Sabin. Mrs. Byron Schultz was

chosen president; Mrs. M. H. Newton was elected president-elect; Mrs. C. C. Whittemore, vice-president; Mrs. B. J. Kelly, recording secretary; Mrs. Howard Murray, corresponding secretary; and Mrs. Gustav Lowenstein, treasurer. Reports of the state convention were given by Mrs. D. F. Aloisio and Mrs. Byron Schultz.

**Nassau County.** New officers of the Nassau County Auxiliary and members of the Board met at luncheon at the North Hempstead Country Club to hear reports and discuss plans for the coming year. The new officers are as follows: Mrs. L. A. Van Kleeck, president; Mrs. N. H. Robin, president-elect; Mrs. C. A. Long, first vice-president; Mrs. J. L. Neubert, second vice-president; Mrs. W. P. Bartels, corresponding secretary; Mrs. T. J. Evers, recording secretary; and Mrs. George Christmann, treasurer.

The program for the year will include a membership tea in September, the Christmas party, card parties, and luncheons. Mrs. Van Kleeck announced that some of the activities of the group which have been discontinued since the war will be revived. Cancer dressings and bandages will be made at next year's meetings. The Board will meet again on September 19.

**Warren County.** Mrs. Burke Diefendorf was re-elected president of the Warren County Auxiliary at the annual luncheon meeting held in The Queensbury. Other officers elected were vice-president, Mrs. W. W. Bowen; recording secretary, Mrs. L. C. Husted; treasurer, Mrs. N. R. Frasier; corresponding secretary, Mrs. D. A. Zurlo. Annual reports were given and very enthusiastic and comprehensive reports of the state convention were given by Mrs. John Griffin and Mrs. Morris Maslon

### PSYCHIATRIC NURSING

Stating that "the need for psychiatric nurses is so great that it cannot be overemphasized," Mrs. Laura Fitzsimmons, Nursing Consultant of the American Psychiatric Association, presents an earnest plea in the article "Facts and Trends in Psychiatric Nursing" in the August *American Journal of Nursing* for the "education of the public to the needs of mental patients, so that funds will be available to raise the care of all mental patients to an acceptable level" and for increasing affiliations in psychiatric nursing for student nurses.

A survey of the nursing care provided patients in eighty mental hospitals in thirty-four states and four provinces of the Dominion of Canada, undertaken by the Nursing Committee of the American Psychiatric Association in 1942, revealed that the ratio of registered nurses to patients ranged from 1:3 to 1:2, 864. The ratio in state hospitals visited

averaged one nurse to 400.48 patients; private hospitals averaged one nurse to 15.67 patients; psychopathic departments of general hospitals averaged one nurse to 7.07 patients.

Some of the facts brought out by the article are:

1. Poor salaries paid in mental hospitals, long hours, and poor living conditions have not been conducive to attracting personnel.

2. In thirteen states, no course of any kind in psychiatric nursing is given, but in one state and the District of Columbia, every student has this experience.

3. The great handicap to the conduct of affiliate courses in psychiatric nursing is lack of persons prepared to conduct such programs.

4. Nurses prepared to work in the field of mental hygiene for the promotion of mental health are needed.

★ "Boys" Town in Reality

In the small village of Woburn, England, the stork has really taken the war seriously. Since the fall of 1942 every baby born to the wives of the place has been a boy. Not a single member of the gentler sex has been in the lot. In fact, only two girls have been born there since September 1941.

Superstitious, prospective mothers yearning for a girl child left the town to bear their children elsewhere—but the records still show that all give birth to boys.

Maybe the unaccountable theory that more boy babies than girl babies are born in time of war may have something to do with the plight of the Bedfordshire village which is now facetiously being called "boys' town."

But the doctors of the local district, baffled by the situation, frankly admit they do not know how to explain the phenomenon

To Prevent Transfusion Reactions...to accurately clarify ETIOLOGY OF ERYTHROBLASTOSIS FETALIS

Our anti Rh serum—artificially produced by the injection of rhesus blood into guinea pigs—offers the highest percentage of correct positive results since many of the anti Rh sera of human origin do not agglutinate all the variants. Memorial Hospital, Catskill, a position from which Dr. William M. Rapp recently resigned after eleven years of service.\*

The new chief of surgery at St. Joseph's Hospital in Yonkers is Dr. Robert Emmet Walsh.

### Newsy Notes

Northern Westchester Hospital's \$500,000 building fund campaign reached a dramatic climax early in July when volunteer workers reported 968 new subscriptions amounting to \$34,827, which sent the grand total of the fund to \$539,256.

Included in this sum was an additional pledge of \$100,000 from the *Reader's Digest*, which was announced by Carll Tucker, president of the hospital and general chairman of the campaign. Half of the *Digest* sum will be applied to the Horace Eddy Robinson Memorial.\*

Representatives of business, labor, medicine, and the clergy started on July 26 a \$350,000 fund-raising campaign for Harlem's Sydenham Hospital and predicted that its new policy would mark the beginning of an era in which no color lines would be drawn in the care of the sick or the training of doctors. Last December Sydenham announced that it would draw its staff from Negro as well as white physicians and nurses and that all facilities would be available to all patients, regardless of race.

City Council President Newbold Morris, honorary chairman of the drive, who was toastmaster at a luncheon at the Hotel Roosevelt, hailed the experiment as a practical application of democratic principles.

Dr. E. M. Bluestone, director of Montefiore Hospital in the Bronx, a member of the fund's sponsoring committee, revealed that the plan had passed the preliminary stages and had been put into operation. "The outlook for a united front toward the sick in our hospitals on a total basis is brighter than ever

Dr. Walsh, who served as a major in the Army Medical Corps in France during the last World War, is physician for the New York Yankees baseball team.

He has been consulting surgeon at St. Joseph's for several years.\*

as a result of the inter-racial principle in Sydenham Hospital," he asserted. "The first in a series of hospital units has been established on the inter-racial principle, with a companion plan that calls for the integration of qualified Negro doctors and other workers in so-called white hospitals."

Dr. Bluestone explained after the luncheon that although no concrete steps had been taken to extend the plan to other institutions, it was believed that success of the project at Sydenham would help to introduce it at other hospitals.

Prof. Eduard C. Lindeman, of Columbia University praised the Sydenham experiment as a "whole-hearted attempt, with no half-way measures or subterfuges" to put inter-racial cooperation on a working basis.

Henry C. Oppenheimer, chairman of the campaign, said that the money raised in the drive would be spent to meet the hospital's deficit for the next four years. Other speakers were the Rev. James Robinson, pastor of the Church of the Master, and Mrs. Ruth Whitehead Whaley, attorney.\*

Funds of \$1,235.74 were realized by the Auxiliary of the Saranac Lake General Hospital as the result of their rummage sale, food sale, and tag day held late in June.

Mrs. Spencer Schwartz was chairman in charge of arrangements for the rummage sale. Mrs. Philip Gingold and Mrs. Samuel Edelberg were in charge of the food sale and Aaron Shapiro was in charge of the tag day.\*

### NO MULTIPLE AMPUTATIONS AMONG YANKS, ARMY SAYS

The Army Surgeon General's Office today dismissed as baseless and irresponsible another "loose talk" rumor circulated since D-Day—that there have been multiple amputations (men who have lost both arms and legs) among Americans on the fighting fronts.

Not a single such case is on record either in Army hospitals in the United States or in base hospitals in England, the Surgeon General's Office said. Even cases of soldiers losing two limbs are rare, only

58 being listed in the last official report on March 21, the War Department office reported.

Army officials added that no amputee is discharged from the service until he has been fitted out with artificial limbs and has been fully taught to use them. Replacements, as more efficient equipment is developed, are made available to discharged veterans without fee through the Veterans' Administration.—*Release from the Office of War Information, July 26, 1944*

### SAMUEL D. GROSS PRIZE

The Samuel D. Gross Prize of \$1,500 will be available this year, according to a recent announcement by the Philadelphia Academy of Surgery. The prize is awarded "every five years to the writer of the best original essay, not exceeding 150 pages, octavo, in length, illustrative of some subject in

surgical pathology or surgical practice found upon original investigations, the candidates for the prize to be American citizens." All essays are to be sent to the Philadelphia Academy in care of the Philadelphia College of Physicians on or before January 1, 1945.

very timely and excellent one. It adequately covers the various problems of "Visual Testing in Industry," "Correction of Visual Defects for the Job," "Visual Skills," "Eye Protection," and "Recent Developments as Related to Industrial Eye Problems."

There is an excellent chapter, written by Dr. Snell, on "Industrial Eye Injuries by Solid Bodies."

The illustrations are well selected; the printing and binding are excellent.

CHARLES A. HARGITT

**Medicine and the War.** (Charles R. Walgreen Foundation Lectures.) Edited by William H. Taliaferro. Octavo of 193 pages, illustrated. Chicago, University of Chicago Press, 1944. Cloth, \$2.00.

This volume is composed of a series of lectures on the part that medicine is playing in this war, couched in nontechnical language. It is more or less a historic analysis of the contributions made to medicine not only in this country but throughout Europe and South America. It will be of especial interest to the laity.

H. M. FEINBLATT

**Synopsis of Neuropsychiatry.** By Lowell S. Selling, M.D. Duodecimo of 500 pages. St. Louis, C. V. Mosby Co., 1944. Cloth, \$5.00.

This book is intended to serve as a specialized guide for students and even specialists in the field of neuropsychiatry. It covers various phases of neuropsychiatry. It covers various phases of neurology and psychiatry, including neuroanatomy, psychological mechanisms, common neurologic syndromes, the psychoses, the neuroses, and mental deficiency. It is reasonably well outlined and the various subjects are very well presented. It is recommended as a practical and helpful guide.

IRVING J. SANDS

**Psychological Medicine. A Short Introduction to Psychiatry.** With an appendix, *Wartime Psychiatry*. By Desmond Curran, M.D., and Eric Guttmann, M.D. Octavo of 188 pages, illustrated. Baltimore, Williams and Wilkins Co., 1943. Cloth, \$3.50.

Despite the experience of World War I, this war again found the services shorthanded as far as psychiatric experts are concerned. In the emergency many physicians who have had no previous experience with mental disorders have had to be impressed into service as psychiatrists.

This English book, whose senior author is on duty with the Royal Navy, is obviously designed to impart some knowledge concerning psychiatric syndromes to men whose duties now require them to have this information. It is brief and to the point, and its only defects must be ascribed to its brevity. The descriptions, as far as they go, are excellent. The dynamics and mechanisms of the mental processes described are either very briefly explained, or not at all. It is to be regretted that no mention is made of those conditions that are on the borderline of psychiatry and the rest of medicine that are apt to reach the attention of the internist first. Dyspepsia, for example, which is an important cause of military disability in the British services, is not to be found in the index.

This readable book will be found useful to physi-

cians who are not psychiatrists who have to brush up on psychiatric nomenclature and syndromes. More extensive tests will be required by students and by those who intend to practice the specialty.

MATTHEW BRODY

**Civilization and Disease.** By Henry E. Sigerist, M.D. Octavo of 255 pages, illustrated. Ithaca, N.Y., Cornell University Press, 1943. Cloth, \$3.50.

Sigerist looks forward to a noncompetitive society in which "every family will have not only its family doctor but also its family health center from which it will be entitled to receive all the advice and help it may need as a public service, and with which it will cooperate in upholding the health of the nation," as in Russia.

The first line of the last paragraph in the final chapter reads: "The problem of financing such health services is secondary."

ARTHUR C. JACOBSON

**A Handbook of Psychiatry.** By P. M. Lichtenstein, M.D., and S. M. Small, M.D. Duodecimo of 330 pages. New York, W. W. Norton & Co., 1943. Cloth, \$3.50.

The book fulfills its purpose of being a handbook of psychiatry for the general practitioner, the nurse, and others who desire a quick reading knowledge of the subject. It reads easily and covers the subject adequately.

The authors have included chapters on psychosomatic conditions and war psychoneuroses which bring these subjects up to date.

Case histories are intelligently interspersed.

J. L. ABRAMSON

**Human Constitution in Clinical Medicine.** By George Draper, M.D., C. W. Dupertuis, Ph.D., and J. L. Caughey, Jr., M.D. Octavo of 273 pages, illustrated. New York, Paul B. Hoeber, Inc., 1944. Cloth, \$4.00.

In this volume Professor Draper's well-known contributions to the study of the human constitution are gathered together and presented in one volume. Although this book is intended primarily for the medical student, no practicing physician, or, for that matter, no social worker or other person whose work brings him into contact with patients can read it without considerable profit.

Draper re-emphasizes an aspect of medicine which, while it dates back to before Hippocrates, has been largely neglected in the past few centuries—namely, the study of the patient as well as of his disease in arriving at a diagnosis and proper treatment. Genetics, growth, heredity, anthropometry, constitutional physiology, the clinical application of constitution studies are all considered in a well-balanced study. Many case histories are appended.

This attitude in medicine is one which could be more profitably studied at the feet of Dr. Draper or some similarly oriented teacher personally, but for those who have not had such an opportunity this book will be an almost acceptable substitute. Students will read it with profit but it will be of even more value to those who have had some experience in clinical practice.

The volume is extremely well written and printed.

MILTON PLOTZ

[Continued on page 1834]

[Continued from page 1832]

**The War and Mental Health in England.** By James M. Mackintosh, M.D. Octavo of 91 pages. New York, Commonwealth Fund, 1944. Cloth, \$0.85.

The author is a splendid example of a physician so psychiatrically intelligent and so gifted in fluent use of English that he drives home the pertinent facts about the facts and factors entering into the mental health status in England during the successive phases of the first four years of World War II. Dr. Mackintosh graphically portrays the psychologic effects of the war upon the civilian as well as upon the soldier. One gains a vivid picture of wartime conditions in England that is very impressive and significantly enlightening concerning cause-effect relationships of war stresses and strains leading to varying degrees of mental ill health. Mention is made of rehabilitation, hospital services, voluntary organizations, professional education, and other means of safeguarding mental health during the postwar period.

This outstanding contribution to mental hygiene literature deserves a wide and thorough reading not only by psychiatrists but also by all those interested in public health and social welfare measures.

FREDERICK L. PATRY

**Sulfonamide Therapy in Medical Practice.** By Frederick C. Smith, M.D. Octavo of 368 pages, illustrated. Philadelphia, F. A. Davis Co., 1944. Cloth, \$5.00.

This book is an attempt to critically review the current literature on the sulfonamides.

The text, however, represents a compilation of statements and findings of others which are usually not assayed by the author's experience. A major objective of the volume is to stress the toxic reactions to the sulfa drugs. This most important subject has not been adequately handled. The literature reviewed is far from complete and the space given to describing methods of counting platelets could certainly have been used to better advantage. Furthermore, the author's minor objections to the local use of sulfonamides will certainly not go unchallenged.

The short appendix covering penicillin is already out of date and should have been omitted.

LEO LOEWE

**Synopsis of Obstetrics.** By Jennings C. Litzenberg, M.D. Second edition. Duodecimo of 405 pages, illustrated. St. Louis, C. V. Mosby Co., 1943. Cloth, \$5.00.

This is the second edition of *Synopsis of Obstetrics* and constitutes an adequate syllabus of obstetric knowledge and practice. The subjects of prenatal care, contracted pelvis, and toxemia of pregnancy have been carefully revised.

This volume should be a real help to all who care to make a rapid review, since each subject is adequately discussed.

J. F. BUTLER

**A Manual of Medical Parasitology.** By Clay G. Huff. Octavo of 88 pages, illustrated. Chicago, University of Chicago Press, 1943. Cloth, \$1.50

In this concise laboratory manual the most important helminthic and protozoan parasites of man are presented briefly with respect to distribution, morphology, life cycle, and laboratory diagnosis.

Seventeen pages are devoted to insects and other

arthropods of medical importance. Several tables and keys for the identification of species are provided. Illustrations are relatively few; there is one excellent colored plate of the malarial parasites of man. The manual is designed as an adjunct to a laboratory course and is not intended to take the place of a standard text or reference work.

ELBERTON J. TIFFANY

**Safe Convoy. The Expectant Mother's Handbook.** By William J. Carrington, M.D. Octavo of 256 pages. Philadelphia, J. B. Lippincott Co., 1944. Cloth, \$2.50.

This handbook for the expectant mother is filled with useful information which will be of value to the mother during her prenatal and puerperal periods and in the care of her infant. Prenatal care, the hygiene of pregnancy, and diet, including a chapter on vitamins, are thoroughly covered.

Chapters on the hospital, labor, relief of pain, and how to care for the new infant are most informative and instructive. The book is written in an easy, story-book style and, among the obstetric facts, the author has woven entertaining anecdotes and historical material about pregnancy and the superstitions which have gathered about it.

*Safe Convoy* will answer many questions about which the expectant mother ponders. It answers these questions in a factual as well as in a delightful manner.

WM. SIDNEY SMITH

**Manual of the Diseases of the Eye.** By Charles H. May, M.D. Eighteenth edition. Duodecimo of 520 pages illustrated. Baltimore, Williams & Wilkins Co., 1943. Cloth, \$4.00.

This edition has again been prepared with the assistance of Charles A. Perara and follows by two years the previous edition. The frequency of the editions and the number of languages into which it has been translated attest to the popularity of this small textbook, which is aimed at the student and general practitioner especially. The chapter on the lacrimal apparatus has been rewritten, and this reviewer is glad to see that slitting the canaliculi is no longer recommended.

There is a good chapter on refraction, which has been rewritten in part by Alson E. Braley. In addition, some illustrations have been omitted and others added. These constitute the chief changes; otherwise the book is the same as before, page for page. It is a book which will probably be found on the shelf not only of the majority of students and general practitioners but of ophthalmologists as well, and deservedly so.

E. CLIFFORD PLACE

**Principles and Practice of Rehabilitation.** By John E. Davis, M.A., Sc.D. Octavo of 211 pages. New York, A. S. Barnes & Co., Inc., 1943. Cloth, \$3.00.

The subject of rehabilitation of disabled service men is one that is the immediate responsibility of the physician. The increasing number of wounded and disabled will require the combined efforts of doctors, social service workers, vocational and recreational specialists, placement advisers, and the interests of the community as a whole. The objective of any rehabilitation program is to restore the physically or mentally disabled veteran so that he may be a useful member of the community and make a

## THE ECONOMY OF "SUBTRACTION"

"Tutoring in Economics"—a feature appearing in *Printers' Ink* gives us a cross-section of scarcity economy in its thirty-eighth lesson which appeared in the April 28th issue.

The effect of scarcity is described briefly and concisely as follows:

"Whatever may be the present supply of anything the world needs or uses, whether it is ample or meagre, if we reduce the capacity for its production,

scarcity for himself, yet desires and does fit in with industrial timidity in other cases as the following sketchy statements will show. Scarcity without demand is powerless.

"1. Scarcity insures high valuation or price in a highly desired thing—gold, precious stones, water in the desert; a pinch of salt may be worth more than a gold coin if salt is not available. Scarcity insures high prices for treasured works of art, fast horses, for display of rare skill in acting or music, but could not do so without vigorous demand.

"2. Scarcity for others, plenty for one's self, is an old, old formula for getting great personal wealth. The holder of the bulk of the mine, the patentee, be held extra wealth sed by destruction, as

in conquered countries where confiscation of means of living makes slaves of the conquered people—has been basically the German search for wealth as seen in the present world war; seeking plenty by causing scarcity to others.

"4. Scarcity created for increasing demand and maintaining prices, i.e., scarcity by limiting or restriction, such as limiting crops or acreage to be cultivated. Such a device is used to avoid cheapening of farm products through unsalable surpluses,

This effects adversely both means to produce and means to purchase products.

"6. Scarcity of supply through monopoly, "cornering" available stocks and boosting prices to excessive profits to those able to effect such monopoly

"Enough has been hinted in these sketchy outlines to suggest the limited benefits of scarcity economy and how it does not foster or encourage growth and all-over industrial expansion; how its outlook is almost always immediate instead of long range; how when any device of scarcity must be used, it should be used with full knowledge that its philosophy is that of subtraction and that world growth and economic evolution call for constant addition and expansion—H. W. D."

[Continued from page 1834]

satisfactory social, economic, and emotional adjustment in the community where he may reside.

The book is a timely and useful presentation of the basic principles involved in the process of rehabilitation. Much emphasis is placed upon the psychiatrically crippled person. However, the physically handicapped are not ignored. It is a good book, one with which every physician should become acquainted. It is recommended to all who have an interest in the subject.

IRVING J. SANDS

**Female Endocrinology. Including Sections on the Male.** By Jacob Hoffman, M. D. Octavo of 788 pages, illustrated. Philadelphia, W. B. Saunders Co., 1944. Cloth, \$10.

This book is actually a compendium of our knowledge of female endocrinology. The text covers the subject completely. The illustrations are excellent and the bibliography exhaustive. The carefully compiled index and a series of clearly described laboratory tests will be found helpful. A good reference book.

CHARLES A. GORDON

## A FEDERAL MEDICAL SYSTEM

A soldier who is wounded in battle or who falls ill is taken without unreasonable delay to a field hospital, where he receives preliminary treatment and his case is diagnosed and classified. Whereupon he is transported to a base hospital for such further surgical or medical attention as he may need. We have nothing quite like this for civilians—not even in cities of metropolitan size. Dr. Thomas Parran, Surgeon General of the United States Public Health Service, proposed a similar organization for the country as a whole when he appeared before Senator Pepper's committee. He would establish outlying clinics in the sparsely populated districts, hospitals back of these, and base medical centers in the States, with the sick transferred from one to the other, as diseases or injuries demanded. Moreover, these clinics, hospitals, and medical centers would serve as teaching institutions for family physicians who are practicing in outmoded ways because there are no local consultants and laboratories to aid them. With the system advocated by Dr. Parran the great hospitals and schools of the large cities and the remote country clinics would be woven into a single fabric. Grants from the Federal Government would enable the poorer States to forge their own links in this medical chain.

In these days of motor-ambulances and automobiles physicians who practice in small communities would thus be able to transport patients who need special care to the nearest clinic or hospital. Patients who could be treated at home would also benefit, because their physicians would have the diagnostic assistance of a local hospital laboratory—something impossible in many rural districts at present. Those who cannot afford to pay anything would resort directly to the local hospital or clinic for free care, much as they do now in the large cities.

If Dr. Parran spoke more boldly than in former years, it is probably because the conviction is deepening and spreading that something must be done to correct long-standing inequalities in medical care. On this all the authorities agree. Despite the fact that medicine has long been "socialized" for mental cases and for many infectious diseases, especially tuberculosis, by Federal, State, and municipal governments, there is general opposition to the abolition of private practice. Dr. Parran's plan should meet with the approval of even the most conservative. It is not a revolution that is proposed but a reorganization and a wider utilization of medical facilities.—*Editorial in New York Times, July 14, 1944. Reprinted with permission of the Times*

## *DOSE* in HYPERTENSION Answer it with **HEPVISC**

High blood pressure brought down to safer levels by gradual, prolonged action of HEPVISC. Also relieves headaches and dizziness.

## DRUG AVAILABILITY

Present conditions of the principle raw materials needed in the making of medicines, have been reported as follows in *Drug, Vitamin and Allied Industries*:

*Glycerine*—The situation has greatly improved and the WFA has suspended its order. Adequate supplies are available.

*Sucrose*—After an increase of 125 percent in the allotment for the last quarter of 1943 and the first three months of 1944, the present basis is 100 percent. The OPA would like to work out a plan for sucrose for drugs on other than the straight quota basis.

*Milk Sugar*—Now under controlled distribution and subject to allocation. Other sugars are critical. Requirements for penicillin are being met in full and the most essential drug uses such as molded tablets have been placed high in the essentiality scale, but

*Sugars*—The situation has greatly improved and the WFA has suspended its order. Adequate supplies are available for production of pounds in ties are available for production of pounds.

*Atabrine (quinacrine)*—Now in ample supply. Present production rates will continue for balance of year.

*Chloral Hydrate*—Due to military requirements, the supply has been short but should become easier in a month or so.

*Vitamins*—The vitamin situation is not entirely satisfactory. Riboflavin is in ample supply. Thiamin hydrochloride is adequate. Vitamin C is more

for all result acid is ble for amide is in short supply. Vitamin A was recently placed under allocation.

*Belladonna*—In ample supply, as is atropine.

*Mercurials* are in abundant supply. Phenol supplies are ample.

*Penicillin*—Approximately 400 million units were produced during the first five months of 1943. In June 1943, 425 million, in July 762 million, August 904 million units. By December of that year the production had exceeded nine billion units. In May 1944, production had reached over 100 billion units.

# Doctor of Medicine...and Morale

HE WEARS the same uniform... He shares the same risks as the man with the gun.

*Right this very minute you might find him in a foxhole under fire at the side of a fallen doughboy...*

*Jumping with the paratroopers... riding with a bomber crew through enemy fighters and flak.*

*Or sweating it out in a dressing station in a steaming jungle...*

Yes, the medical man in the service today is a fighting man through and through, except he fights without a gun.

They call him "Doc." But he's more than physician and surgeon: he's a trusted friend to every fighting man. And doctor that he is... doctor of medicine and morale... he well knows the comfort and cheer there is in a few moments' relaxation with a good cigarette... like Camel.

For Camel, with the fresh, full flavor of its incomparable blend of costlier tobaccos and its soothing mildness, is the favorite cigarette with men in all the services.\*

## First in the Service

\*With men in the Army, Navy, Marine Corps, and Coast Guard, the favorite cigarette is Camel.

### Widely Endorsed in the Medical Management of BILIARY TRACT DISEASE

The administration of Decholin (dehydrocholic acid) or Decholin sodium (intravenous) produces a copious outpouring of thin liver-bile, secreted under increased pressure. This flushing of the bile passages removes mucus, inspissated bile, gravel, and pus if present. The resultant improved drainage is the keystone of present day therapy in chronic cholecystitis, noncalculous cholangitis, hepatic insufficiency, biliary engorgement, biliary dyskinesia. It produces not only appreciated symptomatic relief but also demonstrable objective improvement.

Decholin is contraindicated only in complete obstruction of the common or the hepatic bile duct.

provides 3 pronged attack on SPASM*

Searle Research follows up its introduction of the safe, non-narcotic, antispasmodic, Pavatrine, with the new three-fold-action product

**CLINICAL ADVANTAGES:** Increased and more prolonged spasmolytic action provided through addition of mild central nervous sedation (phenobarbital) to the pronounced musculotropic and neurotropic antispasmodic action of Pavatrine.

**INDICATIONS:** Gastrointestinal spasm, dysmenorrhea, urinary bladder spasm.

• Each sugar-coated tablet contains 125 mg. (2 gr.) of Pavatrine (Searle) with 15 mg. (¼ gr.) of Phenobarbital. Supplied in bottles of 100 and 1000 tablets.

## SESSION OFFICERS 1944-1945

HISTORY OF MEDICINE  
(To be appointed)

PHYSICAL THERAPY  
(To be appointed)

## In Congestive Heart Failure

# Theocalcin

Theobromine-calcium salicylate

Council Accepted

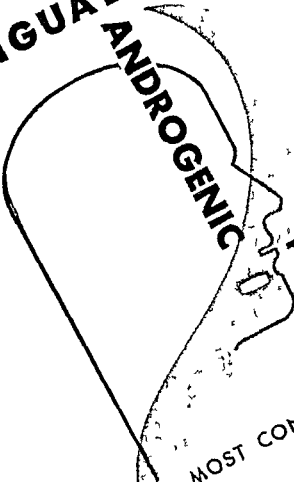

## Diuretic and Myocardial Stimulant

7½ grain tablets and powder. Dose: 1 to 3 tablets, repeated.

## BILHUBER-KNOLL CORP. ORANGE, NEW JERSEY.

# PERLINGUAL ANDROGENIC THERAPY

## MOST ECONOMICAL • MOST CONVENIENT

# METANDREN LINGUETS\*

(METHYLTESTOSTERONE)

Small, hard pressed wafers, especially designed for systemic absorption via the oral mucous membranes, thus side-tracking the liver where partial inactivation of ingested methyltestosterone is known to take place.<sup>1</sup>

Effective in smaller doses, e.g.  $\frac{1}{2}$  to  $\frac{3}{4}$  the amount required when methyltestosterone is swallowed.<sup>2</sup>

Cost of treatment with METANDREN LINGUETS is considerably less than when androgens are administered by injection, implantation or ingestion.

CIBA PHARMACEUTICAL PRODUCTS, INC., SUMMIT, NEW JERSEY

# MARINOL

(IMPROVED FORMULA)

MARINOL (IMPROVED FORMULA) is an homogenized emulsion of cod liver oil and vegetable oils fortified with fish liver oils of high vitamin A potency to which has been added pure vitamin D<sub>3</sub>.

## OUTSTANDING PROPERTIES

**PALATABILITY:** The desirable properties of the fish liver oils have been retained without the disagreeable taste and odor.

**HOMOGENIZATION:** This assures a uniform and stable product that permits of easy miscibility with milk, special formulas, fruit or vegetable juices, or with water.

**HIGH VITAMIN POTENCY:** 5,000 U.S.P. units of vitamin A and 300 U.S.P. units of Vitamin D<sub>3</sub> supply the daily minimum requirements

(FDA) in one teaspoonful.

**LOW COST:** A single teaspoonful daily is a prophylactic dose.

**FOOD VALUE:** Fish liver and vegetable oils supply another desirable property—that of caloric value.

**EASY ADMINISTRATION** is possible because of unusual potency of small dose.

**CONSUMER PRICE:** Bottle of 6 fl. oz., 85 cents. Bottle of 12 fl. oz., \$1.50 (M.P.R. 392). **HOW SUPPLIED:** Bottles of 6 fl. oz. and 12 fl. oz.

# Pediforme

## FOOTWEAR

## for THE ENTIRE FAMILY

Pediforme Shops are not "Ladies' Shops" or "Men's Shops" or "Infant's Shops"—they are equipped to serve your patient of any age and either sex.

From the prenatal care of the mother's feet to rocking chair age, there is Pediforme footwear available to supplement your treatments; or, to fill your prescription for preventing foot troubles.

Our seven busy shops are evidence that the confidence of the profession continues to be justified.

DAVIES, ROSE & COMPANY, Limited  
Manufacturing Chemists,

Boston 18, Massachusetts

"By means of the chewing gum method, I believe the concentration of sulfathiazole can be maintained in the mouth and pharynx for some time, since the solubility of the drug is constant. It is well known that gargles do not reach the nasopharynx, while swallowed saliva does."\*

\*Gertner, Lt. J.. M.C., A.U.S.:  
Correspondence, J.A.M.A.  
122:1204, 1943.

# Local Chemotherapy with

*White's*

# SULFATHIAZOLE GUM

Chewing even a single tablet provides a high, *sustained* salivary concentration of *locally active* sulfathiazole, averaging 70 mg. per cent over a full hour's chewing. Yet *blood levels* produced by even maximal dosage—and even in children—are for the most part too low to be quantitatively measurable. More effective *local* chemotherapy is thus made possible, while *systemic* toxic reactions are virtually obviated.

**INDICATIONS:** Septic sore throat, acute and chronic tonsillitis, pharyngitis, infectious gingivitis and stomatitis, non-epidemic infectious parotitis, peritonsillitis—caused by sulfonamide-susceptible micro-organisms. Preliminary studies indicate that Vincent's disease heals within 48-72 hours following start of treatment.

**DOSAGE:** One or two tablets of White's Sulfathiazole Gum chewed for *one-half to one hour* at intervals of one to four hours, depending on severity of condition. Should patients (children, for instance) find difficulty in chewing a single tablet for one-half to one hour, as many tablets as desired may be successively chewed during the period.

*White's*

# Paredrine-Sulfath<sup>®</sup>

*Provides all three:*

- ① Prolonged Bacteriostasis
- ② Non-Stimulating Vasoconstriction
- ③ Therapeutically Ideal pH

(1) *Prolonged bacteriostasis.* Paredrine-Sulfathiazole Suspension is not a solution, but a *suspension* of Microform crystals of free sulfathiazole. These crystals spread rapidly and evenly over the nasal mucosa, forming a fine frosting of sulfathiazole. This frosting does not quickly wash away,

but remains on those areas where ciliary action is impaired by infection—and thus provides prolonged bacteriostasis *precisely where it is needed most.*

While crystals have been observed on *infected* mucosa many hours after instillation, they are quickly swept from *uninfected* ciliated areas. (The Suspension does not impair normal ciliary action.)

(2) *Non-stimulating vasoconstriction.*

'Paredrine' exerts a shrinking action more rapid, complete and prolonged than that of ephedrine in equal concentration. But it does not produce ephedrine-like central nervous side effects, such as nervousness, restlessness and insomnia.

THE UNIQUE VASOCONSTRICTOR

(3) *Therapeutic pH.* The pH range of Paredrine-Sulfathiazole Suspension—unlike that of the highly alkaline solutions of sodium sulfathiazole—is slightly acid (5.5 to 6.5), and identical with the pH of secretions in the healthy nose

In 191 cases reported in the literature, there was not a single instance of burning, stinging, hyperemia or tissue damage from the use of Paredrine-Sulfathiazole Suspension

(Sulman, L. D., 1943, Silcox, L. E.  
and Schenck, H. P., 1942)

*Smith, Kline & French Laboratories, Philadelphia*

# Paredrine-Sul

## When politeness doesn't pay

Too often patients feel obliged to suppress the normal urge for evacuation while visitors or even physicians are present. When privacy is finally gained, the stimulus may be gone. Another movement has been skipped!

Since absorption of fluid continues in the large bowel, the stool progressively hardens so that when evacuation is attempted, it may require painful straining and irritate tender tissues.

'Agarol'\*Emulsion holds moisture in the stool, provides soft bulk and lubrication, and mildly stimulates peristalsis. 'Agarol' Emulsion does this with finesse—providing the minimal stimulus needed for evacuation. And with 'Agarol' Emulsion there need be no griping, no leakage. . . .

## The Threat of Anemia

### AFTER THE FIRST TRIMESTER

Unless adequately compensated, the dual needs of pregnancy present a two-pronged threat—one against the maternal organism, the other against the forming child. The frequency of hypochromic anemia—usually due to iron and vitamin deficiencies—does not justify its consideration as a “normal” feature of the gestation period. It can and should be prevented by the early institution of iron and vitamin therapy and its systematic continuation through puerperium and lactation.

Heptuna provides an adequate amount

of highly available iron, the fat-soluble vitamins A and D, and the B-complex vitamins (partly derived from liver extract and yeast) so important for optimal iron utilization and maintenance of appetite. It may be depended on to prevent or correct anemia in the mother and to safeguard the infant against the anemia so often developing during the first year in children of anemic mothers. Heptuna, because of its vitamin content, proves valuable also in maintaining the mother's bone structure and in aiding the fetus toward normal dental development.

**J. B. ROERIG & COMPANY**

## IN THE *Eczematoid Lesions* OF INFANCY AND EARLY CHILDHOOD

Among the many advantages of Tarbonis two prove of special interest in pediatric practice. Tarbonis is virtually non-irritant, it is safely applied to the skin of infants, even under the conditions which made the older tar preparations lead to irritation and at times to furunculosis—heat and humidity.

The vehicle of Tarbonis is a vanishing-type cream which exhibits the total active ingredient of the applied quantity to the area under treatment. In consequence, Tarbonis proves therapeutically equivalent, if not actually superior, to other tar preparations of much higher concentration.

Tarbonis owes its high efficacy—demonstrated over a decade of use at one of America's outstanding pediatric clinics—to its special liquor carbonis detergens, of which it combines 5%

with lanolin and menthol in a vanishing-type cream. The process, by which this liquor is extracted from carefully selected tar, is distinctly different—assures greater uniformity—minimizes ir-

SOILING, CARBONIS, VANISHING-TYPE CREAM, LEAVES NO TRACE ON THE SKIN, requires no removal before reapplication. Available on prescription through all pharmacies, for hospital and dispensing purposes through accredited supply houses. Supplied in 2¼, 8 and 16 oz jars and 6 lb containers.

\* \* \*

Physicians are invited to send for clinical test sample and the new, comprehensive

## the **EXTRA FACTOR** in mucous membrane antiseptis

Should an antiseptic be antiseptic only? Or should mucous membrane medication be only contra-congestive? Can any one preparation have BOTH these properties, yet combined with them the more important characteristic of stimulation of tissue defense mechanism?

- The single purpose of most antiseptics is germ destruction. But toxicity to germs of most antiseptics is coupled in much too great a degree with toxicity to membranes—and such toxicity in an antiseptic is especially undesirable when treating infections of the mucous membrane.

ARGYROL provides both antiseptis *and* decongestion. ARGYROL is protective, detergent, pus-dislodging, inflammation-dispelling. ARGYROL is the *physiologic antiseptic*. Write for book on Clinical Application. Please insist on ORIGINAL ARGYROL PACKAGE in ordering or prescribing.

**MADE ONLY BY THE A. C. BARNES COMPANY**

**NEW BRUNSWICK, NEW JERSEY**

# ARGYROL—for physiologic stimulation of tissue defense function

(“ARGYROL” is a registered trade mark, the property of A. C. Barnes Company)

In the increasing incidence of B-complex deficiency—increasing because of greater energy demands and lessened food availability—Noviplex vitamin B complex deserves the physician's consideration. It provides the essential components of the B-complex in approximately the proportions required by the human organism. Since it is largely derived from high potency yeast concentrate, Noviplex provides all the naturally occurring factors, including choline, inositol, and biotin.

# NOVIPLEX

Each capsule of Noviplex contains:

Thiamine hydrochloride .....	1 mg.
Riboflavin .....	1 mg.
Niacinamide. ....	8 mg.
Pyridoxine hydrochloride.....	0.1 mg.
Calcium pantothenate.....	0.2 mg.

plus all other factors naturally occurring in yeast concentrate. Noviplex is supplied in bottles of 100 and 500 capsules.

**THE S. E. MASSENGILL COMPANY**

Physicians are invited to send for the new catalog of Massengill Pharmaceuticals Vitamins and Hormones For Parenteral Administration.

NEW YORK • SAN FRANCISCO • KANSAS CITY

**T**HE recent careful study conducted by Kirwin, Lowsley, and Menning, of the James Buchanan Brady Foundation for Urology, New York Hospital, and published in the December 1943 issue of *The American Journal of Surgery*, reaffirms the many previously published reports emphasizing the clinical effectiveness and complete safety of Pyridium in the symptomatic treatment of common urogenital infections.

In this study of 118 cases of common urogenital infections, routine Pyridium therapy administered for a period of two weeks produced relief of the distressing symptoms in the following percentage of cases: Pain on urination was alleviated or abolished in 95.3 per cent of the cases; burning on urination was relieved in 93.6 per cent of the cases; frequency was greatly reduced or abolished in 85 per cent of the cases; and nocturia was reduced or eliminated in 83.7 per cent of the cases.

The prompt and effective symptomatic relief provided by Pyridium is extremely gratifying to the patient suffering with distressing urinary symptoms. Gratifying also is the confidence in the physician and his therapy which is so evident among patients who are treated with Pyridium.

More than a decade of  
service in urogenital infections

# Facilitates Drainage and Ventilation

The individual afflicted with sinusitis knows too well the pressure pain which follows when sinuses are unable to drain readily.

To relieve such conditions, many physicians now use the new nasal decongestant Sulmefrin, which owes its value to desoxyephedronium sulfathiazole—a combination having the proved vasoconstrictive action of ephedrine-like compounds, with the anti-bacterial properties of sulfathiazole.

Clinical studies have shown that Sulmefrin facilitates drainage and ventilation, generally producing prompt and prolonged vasoconstriction without such side-effects as sneezing, tachycardia or nervousness. It is mildly alkaline (pH ap-

prox. 9.0) and this, according to Turnbull, is preferable for nasal medication because (1) of high antibacterial activity in the pH range 8 to 10, and (2) it allows continuation of ciliary motion for a long period of time.

Sulmefrin may be administered by spray, drops or tamponage. It is supplied in 1-oz. dropper packages and 1-pint bottles. The solution is pink-tinted.

\*Sulmefrin (Reg. U. S. Pat. Off.) is a trade-mark of E. R. Squibb & Sons.

### Plain Talk, I

The medical profession of the nation is faced with a problem of great magnitude and importance. It must *sell* voluntary medical care insurance.

The House of Delegates of the Medical Society of the State of New York has provided for the establishment of a Bureau of Medical Care Insurance with a full-time director and staff to undertake this job for this State. That is all to the good.

Fortunately, this Society is already possessed of a Public Relations Bureau with experience and competence in presenting the views of medicine to physicians and the public alike. It must be used to capacity.

Also this Society has a JOURNAL. Its pages can tell a story. Those pages can tell the story of voluntary medical care insurance. They can tell that story to physicians who need to hear it. They can repeat that story in new words. Over and over. If they are used.

The Society is well equipped with tools for the job. Does it know how to use them? Time will tell. The Federal government

knows how to use them. To sell what we consider an inferior product. Government-controlled medicine.

Many people sincerely believe that government medicine is good. We believe that voluntary medical care insurance is better. Our problem is simple. We must make more people believe that voluntary medical care insurance is better than now believe in government medicine.

But first we must believe that ourselves. Enthusiastically and unanimously. You can't sell what you do not believe in; you can't expect the new Bureau of Medical Care Insurance to sell your insurance to people if you yourself do not believe in it. Certainly, it's your plan. Of course you know that it is medicine's answer to compulsory Federal insurance. You have read that time and again. You have heard it mentioned in your county society meetings—if you were there. You realized, naturally, that your various county and state societies' medical economics committees were "doing something about it." But what have you yourself done about it? Some things

you can hire done. Others you have to do yourself.

If this JOURNAL is to serve you, and the common cause of medicine and the public interest, it must speak the truth. That is essential to good public relations.

Let's go! Not all of us believe enthusiastically in what we have to sell to the public. Some of us are hazy as to what it is all about. Therefore many of us can't talk to our patients or to the public persuasively and convincingly. So we say: get some one to sell the idea for us. That's a step in the right direction, but it is only a step. *Your* services are involved; *you* have to make any voluntary plan work; not only do you have to render the purely medical service to the subscribers, but you also have to do it enthusiastically. Otherwise you are asking your Bureau of Medical Care Insurance, your Public Relations Bureau, and this JOURNAL to help sell a gold brick, not only to the public but to other physicians.

This is plain talk. But we are committed to a voluntary insurance plan and it must work by virtue of the wholehearted participation of all of us in it.

"The people do not want Federal medicine," says Mr. John R. Little.<sup>1</sup> "They only want what they have been told *will result from Federal medicine*. The pressure groups and the politicians cannot enact Federal medicine without the clear will of the people . . . . I suggest . . . you think only of what instrumentality you can supply which will satisfy the people's wants—an instrumentality which will be superior to anything politicians can offer. . . ."

It will be, but only if physicians make it so. This does not mean *some* of the physicians of the State; it means *all* the physicians, and the proper use of *all* public relations media we possess.

## The Voice of the Turtle

In his address to the A.M.A. in June, 1944,<sup>1</sup> President James E. Paullin said, in part,

"During the past year it has been observed that in attempting to present the point of view, as established by the House of Delegates, to many governmental agencies we have been met with the statement that the American Medical Association does not speak for the medical profession of the United States. The reason for this is that some state medical associations have been active in presenting to the public points of view opposed to the policies previously established by the House of Delegates. If the ethical principles and conditions of practice established by the House of Delegates are to be successfully supported, state and county medical societies should bring their differences here for discussion rather than place them before the public. In times such as this it is only by the development of complete unity and support that the views of the medical profession, which have been developed for the best interests of the public and for the advancement of medical science, can be made to prevail. If the purposes and ideals and desires for which we as a medical profession stand are worth while, then there should be the loyal support of every member of all organizations to see that they prevail. . . ."

We agree that there should be as much unity as possible in the medical profession;

but we seriously doubt that "complete unity" would be advisable even if it could be achieved. The views of the medical profession, as indicated by the large variety of resolutions introduced into the House of Delegates, do not represent by any means the views of many county societies.

There is a "loyal opposition" to the A.M.A. and we hope there always will be. When such a group ceases to exist, the plight of American medicine will be serious indeed. We doubt that this opposition is given the hearing and consideration by the A.M.A. which should be accorded it. If it were, there would be little reason for state medical associations to be "active in presenting to the public points of view opposed to the policies previously established by the House of Delegates." When such things occur, there is usually some reason for them. And one reason, which is very obvious, is that, as Parsons<sup>2</sup> says, the House of Delegates is not a truly representative body.<sup>4</sup> Furthermore, much honest disagreement exists as to whether the A.M.A. is fully conscious of public and professional opinion on many mat-

ters Being itself hesitant if not, until recently, obdurate in the matter of presenting the views of the profession to the public, it cannot blame its component units for being willing to do so Says the *Westchester Medical Bulletin*<sup>3</sup> of the 1944 meeting of the House of Delegates

"At a time when scores of thousands of American physicians, both on the home front and in military service, are asking for a vigorous, realistic leadership in medico social matters on the part of the A M A comparable to its undisputed leadership in the scientific field, the new president of the American Medical Association can recommend nothing better for doctors to do than to spend two hours each day speculating with their patients as to the allegedly horrible results of any change in the status quo

"At a time when medical journals throughout the country are appealing to their national organization for resolute leadership, when physicians in Congress leaders in the hospital field, and politicians and publicists friendly to organized medicine are calling with one voice for a sound, progressive national health and medical care program sponsored by the medical profession, the governing body of organized medicine offers nothing better than a reiteration, with minor changes in their wording, of a platform' adopted by the House of Delegates six years ago

The House of Delegates of the A M A, likewise, has taken no action of any kind toward liberalizing the procedures or the organic law of that organization, in such a way as to make it more responsive to the views of what we believe to be a majority of its own membership Such suggestions as the election

of delegates by direct popular vote of the membership in the various states, the provision of initiative and recall through the House of Delegates or by state associations, the establishment of a modern and effective machinery of public relations by the A M A, the abolition of the veto power now held by the Board of Trustees over any actions of the House of Delegates which require the expenditure of funds the proposal to require confirmation by the House of Delegates of the personnel of reference committees appointed by the Speaker of the House, the proposal to require the Board of Trustees to submit an annual budget to the House of Delegates for revision or approval, the proposal that the A M A repudiate its endorsement of that 'Achilles' heel of American Medicine,' the National Physicians' Committee—all these suggestions which have been made in various county and state medical journals throughout the country during the past year received not the slightest consideration by the House of Delegates We do not support all these suggestions but we believe they deserve consideration, in the light of the problems and trials ahead for organized medicine "

As long as the A M A fails to respond to the call, expressed by many societies and their publications, for active leadership in public relations and in other ways, just so long will the loyal opposition feel that it must go direct to the public, having no other choice

<sup>4</sup> Indeed we strain a point to call this system indirectly representative

## Association of Military Surgeons of the United States

Addresses by the nation's three Surgeons General, the chief of the Veterans Administration, the Commanding General of the Second Service Command and New York City's mayor will highlight the Fifty-second Annual Meeting of the Association of Military Surgeons of the United States at the Hotel Pennsylvania, New York City, November 2-4, 1944

Other features of the meeting, which is being arranged under the direction of Association President Col Lucius A Salisbury and Col Charles M. Watson chairman of the convention and program committees, will be forum lectures, discussion panels, military and commercial scientific exhibits, and medical motion pictures

Expected to participate in the forums and discussions are Maj Gen Norman T Kirk, Surgeon General, U S Army, Admiral Ross T McIntire, Surgeon General, U S Navy, Surgeon

General Thomas F Parran, U S Public Health Service, Maj Gen David D W Grant, Rear Admiral Luther Sheldon, Maj Gen G Brock Chisholm, of Canada, Brigadier Generals Frank T Hines, James S Simmons, Charles C Hillman, Raymond W Bliss, Fred W Rankin, Hugh J Morgan, Stanhope Bayne-Jones, Dr Warren F Draper, U S Public Health Service, Dr Chester Keefer, of Boston, and Dr R E Dyer, National Institute of Health

Forum lectures will cover war surgery, chemotherapy, communicable diseases, neuropsychiatry, medical problems in theaters of operation, dental rehabilitation, and equine encephalitis

Topics for discussion panels, which will be integrated with the lectures are "War Wounds, Burns, and Fractures," "Neuropsychiatric Problems," "Treatment and Prevention of Venereal Diseases," "Penicillin and Sulfonamide Therapy,"

"Orthopaedic and Reconstruction Therapy," "Neurosurgical Problems," "Tropical Diseases in the Army and Navy," and "Aviation Medicine."

Separate discussions have also been arranged for dental, veterinary, sanitary, and medical administrative corps officers.

Col. Frederick H. Foucar, of the Second Service Command Laboratory, is chairman of the committee arranging the scientific exhibits, which will include material from Army, Navy, and Veterans Hospitals, the Carlisle Barracks Medical Field Training School, many medical depots, and the Office of the Surgeon General of the Army. All available space for the technical exhibits of commercial firms was disposed of months ago.

The annual banquet, which is to be addressed by a prominent speaker representing the Army,

will be held on November 3, and an entertainment is planned for the night of November 2. The banquet speech and the speeches of the Surgeons General and the Veterans Administrator will be broadcast nationally, while "spot" broadcasts will probably be made by several of the principal forum speakers.

Other committee chairman for the meeting are: Brigadier General Ralph S. DeVoe, (MC), reception; Lt. Col. Howard F. Baer, (SnC), entertainment; Lt. Col. Ralph E. Ladue, (AUS), reservations; Col. George W. Hinman, Jr., public relations; Mrs. Norman T. Kirk (honorary); and Mrs. Lucius A. Salisbury, women's hostess.

The registration desk will be open November 1. Lt. Col. R. E. Ladue, 52 Broadway, New York 4, New York (telephone HAnover 2-5200), should be notified of any difficulty encountered in securing rooms through the Hotel Pennsylvania.

### Competition for Prize Essays

The Merrit H. Cash Prize and the Lucien Howe Prize will be open for competition at the next Annual Meeting of the Medical Society of the State of New York.

The Lucien Howe Prize of \$100 will be presented for the best original contribution on some branch of surgery, preferably ophthalmology. The author need not be a member of the Medical Society of the State of New York.

The Merrit H. Cash Prize of \$100 will be given to the author of the best original essay on some medical or surgical subject. Competition is limited to the members of the Medical Society of the State of New York, who at the time of the competition are residents of New York State.

The following conditions must be observed:

Essays shall be typewritten or printed with the name of the prize for which the essay is submitted, and the only means of identification of the author shall be a motto or other device. The essay shall be accompanied by a sealed envelope having on the outside the same motto or device and containing the name and address of the writer.

If the Committee considers that no essay or contribution is worthy of a prize, it will not be awarded.

Any essay that may win a prize automatically becomes the property of the Medical Society of the State of New York "to be published as it may direct."

All essays must be presented not later than February 1, 1945, and sent to the Chairman of the Committee on Prize Essays of the Medical Society of the State of New York, 292 Madison Avenue, New York 17, New York.

CHAS. GORDON HEYD, M.D., *Chairman*  
Committee on Prize Essays

## *Symposium: The Treatment of Special Infections*

### THE TREATMENT OF INFECTION WITH PARTICULAR REFERENCE TO THE PERITONEUM

SAMUEL C. HARVEY, M D, New Haven, Connecticut

IT IS the purpose of this discussion to consider the common infections which occur in wounds and the logical basis for their treatment, with particular reference to those of the peritoneum. The time at one's disposal will make this presentation both superficial and dogmatic, but it will serve its purpose if it recalls to your minds certain fundamental things about "surgical infections" and arouses a degree of scepticism as to the value of the substitution of "chemotherapy" for procedures well established by long experience.

The infectious agents with which the surgeon contends are ordinarily barred from entrance into the body, and therefore from the production of infection, by the skin and the mucous membranes. It is only when this protective envelope is breached that such organisms proliferate and cause an inflammatory reaction on the part of the host. Some bacteria require a relatively minor damage to this mechanical barrier and, once past it, may quickly get out of control, frequently producing not only a localized but a spreading and even a generalized infection. These are customarily spoken of as having a high degree of virulence and, for the purposes of this discussion, may be termed obligate pathogens. These are usually certain of the hemolytic streptococci and staphylococci. Other bacteria require for their entrance and multiplication more specific and unusual conditions, and more rarely lead to spreading and generalized infections, although their lethal effect in some instances may not be the less deadly. Such are the anaerobes, and most commonly of all certain cocci, particularly the nonhemolytic ones, and gram negative bacilli, for the most part of the colon group. All of these may be appropriately spoken of as facultative pathogens.

The chance of the obligate pathogens being present in or about any isolated and healthy individual is relatively small, but such isolation is rare, and under the frequent contacts of both civilian and military life the possibilities of ex-

posure to these are many. Moreover, the penalty paid for this type of infection in the individual is so serious and the possibility of spread when conditions are right, as in a congregation of wounded patients in a hospital ward, is so great that the precautions against these organisms must be as complete and perfect as conditions will permit. In fact, it is largely to prevent such infections that our detailed ritual during operations has been developed, as well as the technic of the handling of open wounds, which is too often carelessly and ineffectively carried out.

When these precautions are adequately maintained, the transfer of the obligate pathogen directly from wound to wound should not occur and rarely does. Indirectly, from dust and from the upper respiratory tract of those who are infected or from "carriers," the possibility of infection is always present and is increased directly in proportion to the time that the wound remains open and exposed, and to the number of individuals coming in contact with the patient. Therefore, in a severe burn with a large area of skin destroyed, which remains "open" over weeks and even months, the chance of its becoming infected sooner or later with an obligate pathogen is great, while in the wound made and closed in the operating room this occurrence should be rare and then due to a detectable break in the technic.

The facultative pathogens, on the other hand, are always in and on the individual. The skin carries not only a transient flora which may be removed by a thorough cleaning, but a resident one which lives in the sweat glands and hair follicles and cannot be destroyed by any procedure short of the destruction of the skin itself. The latter are, therefore, always present in any wound, and where there is considerable necrotic tissue, as in a blood clot, may produce a relatively mild local infection. Organisms of greater pathogenicity may, of course, be present also in the skin—that is to say, resident there when actual infection exists, as in impetigo or folliculitis, and under these circumstances may be of sufficient virulence when introduced into the open wound to cause serious and even spreading and generalized infection. These are, to a degree, obligate pathogens and are usually hemolytic cocci.

Read by invitation at the Annual Meeting of the Medical Society of the State of New York, New York City, May 11, 1944. Part of a symposium on "The Treatment of Special Infections."

From the Department of Surgery, Yale University School of Medicine, New Haven, Connecticut.

• The transient contaminators of the skin more commonly come from contamination of it with the secretions of the upper respiratory tract and buccal mucous membranes, or with the excretion of the intestine, the feces. Where actual infections or "carrier states" are present in the former, obligate pathogens may be present; in the latter rarely so. Much more commonly they are facultative pathogens and cause infection only when the right conditions are present.

The obligate pathogens possess a facility for living and proliferating within living tissue; the facultative pathogens require the presence of dead tissue, although when once established they may, by their own action and the response of the host, cause further necrosis and thus become self-perpetuating. The newer chemotherapeutic agents interfere with the enzymatic processes essential to the growth of the bacteria, and therefore are effectual with the obligate group, while the antiseptic agents which are protein coagulants kill living cells, produce necrotic tissue, and thus form a favorable basis for the growth of the infecting organisms. The obligate pathogen is, then, in short, an organism which grows within the body and is sensitive to the antibiotic agents, while the facultative pathogen is dependent upon dead tissue for its persistence and in general under these conditions is not responsive to these agents.

In how far do these somewhat arbitrary statements correspond with experience? It was generally recognized, on the basis of the experience of the previous World War, that removal of all devitalized tissue before infection became established prevented the development of this in a very high percentage of instances. This was in spite of the fact that such wounds were heavily contaminated with a great number of bacteria of many types. However, there always remained a certain number of instances in which the organism present was highly pathogenic or necrotic tissue was inadvertently left behind, so that it was unsafe to close such wounds, particularly when, as was usually the case, they could not be followed closely and carefully. Consequently, in frequency proportionate to the time they remained open, they later became infected, and some with streptococci or staphylococci of high virulence which gave rise to spreading and generalized infections leading in many instances to death. The same situation seems to be fundamentally true today, judging by the reports of the units working under the supervision of the committee on wound infection of the National Research Council under Dr. Meleney. The use of sulfonamides in the wounds has, in the opinion of all the investigators, caused no improvement over those wounds not so treated, so far as the local

infection is concerned. On the other hand, there is a strong impression that the spreading and generalized infections have been much less frequent than might have otherwise been expected. This is counter to the general surgical opinion and practice, and is violently contested by some. It may be the fact that the local application of the sulfonamide provides a method, through its absorption, of establishing a fairly effective blood level, which prevents the development of spreading and generalized infections but permits the persistence of local infection as long as necrotic tissue persists, whether from the original injury or as the result of the necrotizing effect of the organism concerned. If this is the case, it would be preferable to give the drug systemically, where it can be more carefully controlled. Curiously enough, with the concentration of thought upon the local effect it does not seem to have been used in this fashion without application to the wound, and therefore the final evidence is not at hand. I believe, however, that it still remains of the greatest importance to remove necrotic tissue by adequate drainage, excision, débridement, and other appropriate surgical measures in the wound itself and in addition to use the sulfonamides or penicillin systemically rather than locally for the prevention and treatment of potential spreading and generalizing infections. By these means both the obligate and facultative pathogens are cared for as well as can be done at the moment.

How, then, does this apply to peritonitis? In the first place, aside from infections with the gonococcus and with the streptococcus or with the pneumococcus in the relatively rare primary peritonitis, the contaminants are derived from the fecal depot of bacteria. With an ulcerative lesion of the gastro-intestinal tract and occasionally in a fulminating inflammatory lesion, there may be obligate pathogens present, but in the great majority of instances the infecting agents are facultative, and their pathogenicity is a result of the situation in which they are found. This is in a closed space within the body, the lining membrane of which is mesothelium which reacts at once to irritation by the passage of fluid through it into the peritoneal cavity. This reaction varies, undoubtedly, according to the individual and the organisms concerned. Sometimes it is small in amount and contains a high content of fibrinogen, so the peritoneal surfaces become plastered together at an early moment, walling off further extension of the infection and providing means for the phagocytic cells to reach and deal with the infectious agent. In other instances the exudate is profuse, separates the peritoneal surfaces, and at the same time provides excellent pabulum for the further growth

and extension of the organisms. As this takes place a process, similar to cellulitis in soft tissues elsewhere, occurs in the intestinal wall beneath the peritoneum, leading to inhibition of peristalsis, distension, and all the manifestations of the so-called adynamic ileus. This, with the continuing formation of putrid peritoneal fluid and the absorption of the products of broken-down protein, as well as the loss of fluid into the peritoneal cavity, leads in the more fulminating instances to peripheral circulatory failure and death, while the same end is reached more slowly in others by reason of what is essentially intestinal obstruction. The facultative pathogen produces in this way the necrotic medium in which it grows, and any measures which damage the peritoneum and increase the exudate favor its development, while those taken to decrease contamination and the available media for the growth of organisms lead toward the overcoming of the infection or at least the confinement of it to limited areas.

It is obvious that the first indication is the shutting off of the source of infection or, if this is not possible, the exteriorization of it by establishing drainage from that point out of the peritoneal cavity. Second, it is important to evacuate as much of the exudate as can be done without additional trauma to the peritoneum. This is usually accomplished inadvertently when there is a large quantity present, when the peritoneum is opened, and when the accumulation is still localized, during the limited exploration that is necessary to reach the source of the contamination. This removal of fluid allows the peritoneal surfaces to collapse together and become adherent, and provides the best opportunity for walling off the infection, at times forming abscesses which may be drained later when they are well developed. This is not a "toilet" of the peritoneum, but a recognition of the fact that the opening of it and a gentle exploration, just sufficient to permit of the control of the source of the contamination, at the same time decompresses the abdominal cavity and leads to the clearance of fluid which would serve as a source for the growth of the facultative pathogens. In no instance should adhesions be separated or exploration carried out with a view to removing the fluid *per se*, for the damage done is greater than the benefit acquired.

When the superfluous fluid has escaped, the intestines fall together and against the parietal peritoneum, frequently leaving pools of fluid in the pelvis, beneath the liver, and under the diaphragm as well as smaller pockets elsewhere. As Yates<sup>1</sup> showed, many years ago, it is impossible to maintain continuing drainage of the peritoneal cavity, for the intestines rapidly become

adherent about the drains and wall them off. Perhaps the best policy is to drain the source of contamination if this is not satisfactorily controlled or if the soiling has been a gross one so that a focus of contamination persists, and to drain walled-off areas which are potential abscesses. When fluid continues to work its way out through the peritoneal incision at the close of the procedure, drainage, which will admittedly be temporary, for a few hours only, may serve further to decompress the abdomen, but otherwise the peritoneum should be closed, with drainage of the abdominal wall only. This practice corresponds closely to that found to be preferable in dealing with infected bursal spaces such as the knee joint, and in principle does not differ from the well recognized methods employed in treatment of infection of the pleura.

Most of what has been said so far concerning the treatment of peritonitis will be accepted, I imagine, without too great disagreement. Much more controversial is the employment of chemotherapy. Antiseptics in wounds had their day so long ago that but few surgeons recall their use, and they were discarded because of the damage to the tissues, which favored rather than prevented further infection. As in wounds, the advent of the "antibiotics"—the sulfonamides and penicillin and similar agents—has enlisted the interest and aroused the enthusiasm of many of us. In considering these it is important to keep in mind that they do not destroy organisms—in other words they are not bactericidal—but interfere with their metabolic processes so that they do not multiply—that is to say, the effect is bacteriostasis. Under these circumstances, when the organisms are within viable tissues their destruction by the normal phagocytic and antibacterial mechanisms is accelerated. These agents are then most effective when the bacterium is, as the saying goes, "invasive" and least so where it is in necrotic tissue or in putrid exudates.

Without doubt, in many instances of fulminating peritonitis an obligate pathogen is present although obscured by the overgrowth of other members of the intestinal flora, and the systemic use of sulfonamides or penicillin will check its progress. When the infection is by facultative pathogens which are for the most part relatively unsusceptible to the antibiotics, particularly in the presence of a disintegrating protein exudate, one must rely upon the mechanical procedures for aiding in the walling off and control of the infection. Application of one of the sulfonamides locally within the peritoneal cavity seems, then, illogical and not without its dangers. The least harmful one is the most soluble and most rapidly absorbed, namely, sulfanilamide, and therefore

• The transient contaminators of the skin more commonly come from contamination of it with the secretions of the upper respiratory tract and buccal mucous membranes, or with the excretion of the intestine, the feces. Where actual infections or "carrier states" are present in the former, obligate pathogens may be present; in the latter rarely so. Much more commonly they are facultative pathogens and cause infection only when the right conditions are present.

The obligate pathogens possess a facility for living and proliferating within living tissue; the facultative pathogens require the presence of dead tissue, although when once established they may, by their own action and the response of the host, cause further necrosis and thus become self-perpetuating. In other instances the exudate is profuse, separates the peritoneal surfaces, and at the same time provides excellent pabulum for the further growth

are not susceptible and the infections caused by them are not amenable to penicillin therapy. These include the typhoid-dysentery-colon group, pyocyanus, proteus, and Friedlander infections, as well as infections with the tubercle bacillus, monilia, malerial parasites, and others.

As to administration of the drug, there are a number of differing opinions as to dosage and routes of administration. We have no arguments, pro or con, with these, but we insist on effective, nonwasteful doses and effective routes of administration. It has been shown that penicillin loses its effect when in contact with the acid gastric contents and in the rectum, so these routes are not used. Duodenal instillation by tube or enteric coated capsule has been tried but is unreliable.<sup>2</sup> Subcutaneous administration has been used, but the irregularity of absorption and the local pain make this undesirable. To be effective penicillin is administered either intramuscularly or intravenously or applied directly to the wound. Except in the very acutely ill when we use intravenous therapy, we use intramuscular injection routinely. The ease of administration by nursing personnel and the high efficacy of the route as compared to the others have led us to this decision.

The dry penicillin powder is put into solution in sterile isotonic solution of sodium chloride or 5 per cent glucose solution. For convenience of injection the usual solution is made so that each cc contains 5 000 Oxford units, although other strength solutions may be used. For local application the usual strength is 250 units per cc, although this may also be varied.

Because of the very rapid excretion of the drug, injection must be made either continuously or, at the longest interval, about every two hours in intravenous therapy, or about every three or four hours in intramuscular therapy. It is known that as much as 50 to 60 per cent of the total injected dose may be detected in the urine after any form of therapy, and this occurs within two to four hours after injection.

For local application to wounds, the solution of 250 units per cc is used to saturate gauze packs which are inserted into the wound once daily. We have never used any powder form of the drug for local use, but this can be done by diluting the penicillin in some powder vehicle and dusting this into the wound.

The question of dosage is still under considerable debate, with estimates varying through a large range. We have determined an effective schedule of dosage for the various infections and present it as effective doses rather than minimal or maximal doses. The dosage of any particular case depends on the bacteriology of the wound or disease, and on the condition of the patient. The

effective level for the most susceptible infections, such as those caused by the beta hemolytic streptococcus and pneumococcus, has been determined to be in the neighborhood of 90,000 to 120,000 units per day. The staphylococcus requires a dose of about 200,000 units per day or higher. The dosage may be suggested by *in vitro* tests, comparing the activity of penicillin against the infecting organism to that of penicillin against a known test organism. In the very acutely ill patient, however, one tends to use a somewhat higher dose than the one indicated, later dropping to the usual dose when improvement is noted, particularly in staphylococcal and clostridial infections where there is some danger of the organism's becoming penicillin-resistant.

As concerns the toxicity of penicillin, it can be stated that no serious complications or deaths have been encountered to date. Penicillin as it is delivered to us today has no pyrogenic matter in it, but is at best only about 50 per cent pure, so what reactions have been noted may perhaps be caused by the impurities rather than by the penicillin itself. In a few cases a low fever has been noted in the first three to five days. This never exceeds 1 or 1½ degrees and never upsets the course of the patient, and recedes of itself. Urticaria has been encountered anywhere along the course of treatment and as long as nine days after treatment. This may be mild or severe and responds somewhat to the usual measures but usually persists three to five days and disappears regardless of the stopping or continuing of penicillin. Thrombophlebitis has been encountered, chiefly at the site of intravenous injection with concentrated solution of penicillin. We suspect that much of this is directly associated with poor venipuncture technic rather than with the drug. Other minor transitory reactions have been seen very occasionally, but never have been the cause of alarm: headache with flushing of face and faintness, unpleasant taste, tingling of the testes, transient eosinophilia, and, rarely, slight rise in the nonprotein nitrogen. These are all so mild and evanescent as to be disregarded as serious complications. Burning and pain at the site of intramuscular injection is rather common and varies greatly with different lots of the drug. Much of this can be eliminated by filtration through a Seitz filter. Most of these reactions are very inconstant and do not occur with all lots of the drug, so in many cases we feel the impurities present in the drug are responsible.

Systemic diseases without external manifestations, such as pneumonia, bacteremia, gonorrhea, and cellulitis, are treated by systemic therapy alone with dosage and duration of treatment appropriate to the type of infection. Infections of the body cavities, such as the chest and joints,

may be treated by injection of penicillin directly into the cavity involved, although systemic penicillin is usually indicated for a few days. Extensive wounds and compound fractures present a different problem than most other infections. It is quite obvious that soft tissues which are infected but which have good blood supply can be adequately treated with penicillin without extensive surgery. However, it is a proved fact that a wound cannot be sterilized if infected dead bone is present or foreign bodies, such as pieces of clothing, are left in the wound. In these cases adequate surgery must be done to remove this foreign and dead matter and the wound so revised that local penicillin may be adequately used. In such a program of treatment systemic therapy is employed to clear up and protect against the infectious process about the wound, or spreading from the wound in tissue planes or lymphatics. Local application of penicillin is then employed to take care of the localized infection. Usually a combination of systemic plus local application is the plan of treatment.

The general condition of the patient is evaluated and any necessary treatment is given to put the patient in optimal condition for operation. Penicillin is then started and continued for from two to five days preoperatively. Débridement in the acute compound fracture is performed without delay when the patient's general condition will permit, but penicillin therapy may be instituted while the patient is being prepared for operation. Operation is then performed and the necessary surgery is done, pus is drained, dead bone, sequestra, and foreign bodies are removed, and reduction of a fracture may be accomplished. The operative site is packed loosely open, with adequate drainage provided. The wound is not dressed, usually, until three to six days later, but systemic penicillin is carried on during this period. Early dressing encourages bleeding and organisms thrive on the clots, so this is avoided. If after dressing there is no reaction about the operative site and all exposed cortical bone is covered, then systemic penicillin is stopped and the wound is dressed once daily with local penicillin. This is continued until the wound is healed or a secondary closure can be done.

The patient with the acute compound fracture is usually a good surgical risk at the time of his injury. Shock and loss of blood may lower his general resistance, and this is certainly true if infection develops. With severe infection and especially with chronic sepsis in which the metabolism has been upset, other factors enter into our care of the patients, since they are found to heal their wounds and fractures slowly and are, in general, poor surgical risks. These patients

with chronic sepsis have often had a profound upset in the general body economy, as evidenced at times by great weight loss, anemia, lowered blood pressure, and general debility. They are almost invariably in negative nitrogen balance. Elman<sup>3</sup> and others have shown the importance of positive nitrogen balance in maintaining and restoring good general health. It can readily be shown that healing of wounds, both soft-tissue and bone, depends in large measure on the positive nitrogen balance, particularly in those cases where the usual protein stores have been depleted by long-continued sepsis. Dietary measures, even supplemented by parenteral hydrolysates and amino acids, do not quickly make up the deficiency, since excretion rises with increased intake.

The reason for this was noted in another finding. We have known that there is progressive anemia in chronic sepsis, but the extent of this was not appreciated fully. The routine laboratory tests usually indicate the deficiency, but not to the extent it is really present, since we have been determining only the percentage composition of blood rather than the total circulating amounts present; and, in the final analysis, this is the important thing. Thus a patient's hemoglobin, reported to be 13 Gm. per 100 cc., is deficient, but not alarmingly so. However, if his blood volume is determined and is found to be short, then the deficiency may be very great. Thus, if a patient's blood volume is 5,000 cc., when it should normally, for him, be 7,000 cc., his total circulating hemoglobin is 650 Gm. instead of the 1,050 Gm. it should be. Also, other elements of the blood would probably be deficient to a similar extent. Thus, without knowing the blood volume we cannot estimate the true condition of the patient.

As a matter of fact, in patients who have been septic over a long period of time diminished blood volume is a constant finding, along with a severe hemoglobin deficiency. This hemoglobin deficiency must be restored to normal before protein is returned to the normal storehouses. Therefore, even in a patient showing a positive nitrogen balance, healing is slow or absent until blood hemoglobin is restored.

The blood volume may be determined by the Evans Blue Dye method described by Greger<sup>4</sup> and others. This involves the injection of a known quantity of the blue dye, withdrawing samples of the blood, and determining the concentration of dye in the plasma. This is readily done by colorimetric determination on the plasma. From this the quantity of plasma can be determined and, by use of the hematocrit, the total blood volume may be calculated. Normal volume is calculated as 9 per cent of the usual body

weight in kilograms. The extent of the deficiency can thus be noted.

In the normal person decrease in blood volume such as that caused by acute hemorrhage and other causes is rapidly made up by inflow of fluid from the fluid held in the intercellular spaces. Quite apparently, this normal action is interfered with in some way in chronic sepsis, where an almost constant finding is an increased interstitial fluid volume accompanying the decreased blood volume as noted above. The exact cause for this and its significance is not well understood, but it is evidently an integral part of the chronic sepsis, and is probably another evidence of the upset in the total metabolism of the patient. With restoration of blood volume, control of sepsis, and clinical improvement of the patient the interstitial fluid volume is found to return to normal. Interstitial fluid volume may be determined by the thiocyanate method as described by Crandall and Anderson<sup>5</sup> and others, somewhat like the blood volume determination by colorimetric method. More will be learned about this interesting phase of sepsis as more work is done on it. Incidentally, this increase in interstitial fluids masks somewhat the true weight loss in sepsis.

It is obvious, then, that the great immediate need in these chronically septic patients is either whole blood or hemoglobin. Whole blood can be supplied by transfusion as usual but it becomes more apparent that we must revise upward our ideas of the amounts needed if we are to do the most good. If the fluid volume is normal but the hemoglobin is low, this can be remedied by giving resuspended red cells which are ordinarily lost in the process of making plasma. Substitutes for hemoglobin do not work out so well, so at present the red blood cell itself is the best source of hemoglobin.

When blood volume and hemoglobin lack is made up and sepsis is controlled by penicillin and other measures, the patient is a much better operative risk than he was before. Then with a high calorie, high protein diet, the nitrogen balance becomes strongly positive and protein is stored in the muscles and other storehouses, as evidenced by weight gain and increase in muscle mass. From then on wound healing is rapid and progressive to final healing.

In the treatment of the acute compound fracture penicillin plays an important role, that of an effective antibacterial agent. Penicillin therapy cannot replace the usual treatment and must be accepted as a mere adjunct in the management of each individual case. Good first aid consisting of morphine, adequate splinting, and blood plasma, must be insisted upon. The patient is made ready for débridement as soon as possible. The

details of this operation do not need discussion, but it should be emphasized that the débridement should be carefully and adequately performed.

All foreign bodies and devitalized structures should be removed and considerable discretion should be exercised in determining the completeness of the débridement. A needless sacrifice of bone fragments and soft structures must be avoided if the surgeon is reasonably certain that the circulation is adequate. A carefully performed débridement calls for a thorough mechanical cleansing of the wound as well as a constant irrigation with sterile water throughout the operation. The fracture should then be reduced, but internal or external fixation must never be used. Closure of the compound fracture is strictly forbidden. Vaseline gauze should be used to protect the wound, but it must not plug the wound sufficiently to interfere with drainage should infection subsequently develop. The reduction is then maintained by the application of a plaster of paris cast or traction.

It is our practice to débride the acute compound fracture as soon as possible. Penicillin therapy is started prior to operation. Morphine and plasma are used to combat shock. The importance of blood transfusion cannot be emphasized too greatly, for these patients have usually lost blood. We routinely administer blood and plasma postoperatively to maintain the patient's blood volume and nutritional status, and we feel that this decreases the incidence of infection. The wound is not closed. The unpadded cast is not used. The severe case, particularly if the fracture is markedly comminuted and associated with excessive soft-tissue trauma, is treated by skeletal traction following the débridement, as this permits frequent inspection of the extremity. With the benefit of penicillin, it is believed that even the case which does not come to surgery until six to twenty-four hours after the time of the injury may be reasonably expected to heal without infection.

The septic compound fracture needs adequate drainage. There are frequently associated foreign bodies and sequestra. The septic patient is not a good surgical risk. These patients do well with penicillin, a high calorie and protein diet, and repeated blood transfusions. Within a few days the infection begins to subside and the patient's general nutritional status has improved to the extent that surgery is permissible. Adequate drainage is then established and the wound is carefully explored and all foreign bodies and sequestra are removed. Sequestra will prevent wound healing, but with the use of penicillin and a well-planned preoperative program, the patient may quickly be made ready for a safe perform-

ance of necessary surgery. The septic compound fracture with deformity may occasionally be reduced, but this procedure should be confined to selected cases. The morbidity may be materially lessened if reduction can be accomplished without waiting for complete wound healing. The wound should never be closed following sequestrectomy, although secondary closure may be permissible in the occasional case.

As we see the orthopaedic casualties returned to this country, we are impressed with the fact that our major problem is the management of the compound fracture. Efficient first aid, plasma, blood transfusions, the sulfonamides, and the open-wound method of treatment have served to minimize infection. More important, however, these principles have saved both life and limb in many instances. We have been convinced that the severity of infection has been in direct proportion to how early and how effectively the above dictates of treatment had been instituted. It has also been our conclusion that the present low mortality and morbidity rate in compound fractures must be attributed to the open-wound method of treatment.

Our experience in the use of penicillin leads us to believe that it is a more effectual antibacterial

agent than the sulfonamides, in both the prevention and cure of infection. It has likewise proved valuable in the prevention of reinfection following reconstructive operative procedures. This factor has made it possible to perform major surgery sooner after complete wound healing than had been the case with the use of the sulfonamides. Penicillin therapy must be recognized and accepted as an adjunct only in the management of a surgical problem. Penicillin cannot, and therefore it should not be expected to replace a well-planned surgical program. Further clinical and experimental studies are needed for a more complete evaluation of the usefulness of penicillin.

In conclusion, penicillin plays the role of an effective antibacterial agent in the treatment of compound fractures, but only as an adjunct to a well-planned surgical program.

## THE PROPHYLAXIS AND THERAPEUSIS OF CLOSTRIDIAL INFECTIONS (GAS GANGRENE)\*

ANDREW H. DOWDY, M.D., Rochester, New York, ROBERT L. SEWELL, M.D., Fort Worth, Texas, and JAMES G. VINCENT, Rochester, New York

SINCE 1939 we have been intensely interested in experimental "gas gangrene." We have studied over 1,400 dogs in which the disease has been experimentally produced. It is not the purpose of this paper to give a complete report upon all phases of our work at this time, nor is it possible to do so, as the studies are still in progress. A variety of agents have been tested, namely, roentgen therapy,<sup>1,2</sup> subcutaneous and

intramuscular oxygen,<sup>3</sup> sulfadiazine, sulfathiazole, sulfanilamide, penicillin, and pentavalent antitoxin. This report will be confined to the aforementioned sulfonamides, penicillin, and pentavalent antitoxin.

We have found the dog a very satisfactory animal for the study of experimental clostridial infections. One not infrequently finds the disease arising in this animal as a result of its normal environment. The experimental disease in dogs more closely simulates the disease as seen in humans than it does in the smaller animals. The infection tends to remain localized in the involved limb, with an increasing degree of systemic reaction, culminating in a toxic death in 93.4 per cent of a series of 377 untreated control dogs in which the disease had been established.

Our method of producing the disease, while not analogous to that occurring in humans, is free of complicating and variable factors such as anesthesia and surgical trauma. We are consequently enabled to evaluate the efficacy of any particular therapeutic agent as balanced against

the resistance of the host and the virulence of the causative organism.

A study of the pathology of 69 of these dogs<sup>1</sup> further confirms our opinion that the disease as produced presents a consistent picture. The disease in all control animals was severe according to the degree of injury occurring at the local site of inoculation, in the cardiac muscle, and in the liver, in the order named. In most of the treated animals subjected to pathologic study the inoculated site showed a remarkable repair of the previously damaged muscle. The heart showed an occasional area of necrosis with good organization. In general the liver was undamaged. The kidneys in both the control and treated groups of dogs were remarkably free of damage.

## Experimental

**Infectious Agents.**—The infectious agents were virulent cultures of *Cl. perfringens*, *Cl. septicum*, *Cl. novyi* (two strains), and *Cl. sordellii*, employed either singly or in combination. The combined clostridial inocula, in addition, contained a strain of *Staphylococcus aureus*. Douglas medium<sup>5</sup> containing chopped beef heart and sealed with a vaseline plug was used for culture and storage of the clostridia. The staphylococcus culture was grown in plain Douglas broth.

**Inoculation.**—The amounts of the inocula for the various organisms were as follows:

Approximate Number of Vegetative  
Organisms and Readily Germinat-  
ing Spores

The mixed inocula contained equivalent fractions of the individual inocula and *Staph. aureus* in the ratio of 1:20. This mixture of cultures produced such a great increase in virulence that the amount of injection had to be reduced to 0.03 cc., which was one thirtieth of the size to be expected from simple summation of the individual inocula. Subsequent studies proved that the presence of *Staph. aureus* was not responsible for this increase in virulence.

The amounts of the various inocula were determined from a series of standardizations on dogs after preliminary standardization on guinea pigs. The inocula were adjusted to bring about death in a high percentage of the control dogs, without producing an overwhelming infection which would not respond to prophylactic or therapeutic treatment. The organisms were grown in pure culture and, for the mixed inocula, combined just before the inoculations were made. All inoculations for dogs were made with unwashed and undiluted culture. Prior to the injection, the

inoculum was mixed with one tenth of its volume of 1:1,000 adrenalalin chloride. A clipped area on the right hind leg was sterilized with iodine and alcohol, and the injection was made deep into the thigh muscles by passing the needle down until bone was encountered.

**Bacteriologic Verification of Infection.**—In the infections produced with the individual clostridia, pure cultures of the inoculated organisms could be isolated from the wound fluids at will. The recovery of the causative organisms from the infections produced by a mixed inoculum was more complex. The difficulties of separating such closely related organisms are enhanced by the fact that they apparently form a mixed colony growth, that *Cl. perfringens*, the most easily cultured of the group, tends to overgrow the agar plate, and that one or more species in a mixed infection may be manyfold more numerous in any particular area of the infection. In the earlier experiments with mixed inocula not all of the organisms of the mixture could be recovered from a single sample of wound fluid. However, later work has shown that these failures were due to inadequate bacteriologic methods. At the present time, with the application of heat shock to the wound fluid, recovery of *Cl. novyi* and *Cl. perfringens* from a mixed infection of the two organisms has been routinely accomplished.

## Prophylaxis

**Drug Administration.**—All treatments were systemic and the drugs were administered intravenously just prior to inoculation. The definitive agents employed were sulfadiazine, sulfathiazole, and sulfanilamide. Penicillin, in a single pilot experiment, was used prophylactically against *C. novyi*, but this agent was largely reserved for experiments in therapeutics.

Sulfadiazine was administered as the sodium salt in a 5 per cent solution. The initial dose was 3 cc. (0.15 Gm.) per kilo of body weight and additional amounts were administered in order to maintain the blood concentrations as nearly as possible between 15 and 20 mg. per cent for a three-day period. No supplementary dosage by mouth was necessary to maintain these levels. Sulfathiazole was administered intravenously as the sodium salt in a 5 per cent solution, but was supplemented by oral doses of the free acid to maintain blood levels at 15 to 20 mg. per cent. The initial intravenous dose of the sodium salt was 4 cc. (0.2 Gm.) per kilo of body weight. The initial oral dose was 0.5 Gm. per kilo of body weight administered approximately one hour after the intravenous dose. The maintenance dosage was both oral and intravenous. Sulfanilamide was administered per se in an 0.8 per cent solution and supplemented with oral doses. The

initial intravenous dose was 25 cc. (0.2 Gm.) per kilo of body weight and the succeeding intravenous and oral doses were adjusted to maintain the blood levels at 15 to 20 mg. per cent for the three-day treatment period.

**Blood Levels.**—Blood levels were taken on each dog, usually before and after each drug administration to provide maximum and minimum levels. Frequent intervening blood levels were taken. On the average fourteen to sixteen levels were taken on each dog over the three-day treatment period. Rapid changes in a dog's toxicity with consequent differences in hemoconcentration and elimination increased the difficulties in maintaining constant blood levels. Analysis of the blood concentration curves indicates that sulfathiazole was most difficult to maintain at the desired levels while sulfadiazine was the most easily controlled.

**Results.**—The three-day treatment period was followed by seven days of observation, making an experimental period of ten days. Survivals were based on that period. Groups of 25 dogs were treated with each of the three sulfonamides against each of the four clostridial species, and an untreated group of 25 dogs was used as a control for each species. With Cl. perfringens there was a 12 per cent\* survival of the controls; with Cl. septicum there were no survivals; with one strain of Cl. novyi there was 4 per cent survival, and no survivals with the second strain. Cl. sordellii infection allowed a 12 per cent survival, and the mixed clostridial infection of Cl. perfringens, Cl. septicum, Cl. sordellii, plus Staph. aureus, but without Cl. novyi (Mixed Inoculum I), allowed a 6.6 per cent survival.

Sulfadiazine proved to be the most effective prophylactic agent, with 92 per cent survival against Cl. perfringens infection, 72 per cent survival against Cl. septicum, 80 per cent against Cl. sordellii, but only 4 per cent against Cl. novyi. Sulfathiazole was next in effectiveness, with 44 per cent survival against Cl. perfringens, 28 per cent survival against Cl. septicum, 32 per cent against Cl. sordellii, and with no survivals against

Cl. novyi. With sulfanilamide, the survival against Cl. perfringens was 20 per cent, 40 per cent against Cl. sordellii, and zero against Cl. septicum and Cl. novyi (Table 1).

Cl. novyi proved extremely resistant to the action of the sulfonamides.<sup>6</sup> A second strain was used to check this resistance and in this case there were no survivals. When the inoculum of the first strain was reduced from 0.5 cc. of culture to 0.15 cc., sulfadiazine produced a 36 per cent survival in 25 dogs. However, there was a control survival with this inoculum of 20 per cent.

Prophylaxis was tested with the three sulfonamides against Mixed Inoculum I of Cl. perfringens, Cl. septicum, and Cl. sordellii, made up of equivalent fractions of their individual inocula and Staph. aureus in a ratio of 1:20 of culture volume. The inoculum with this mixture was reduced to one thirtieth of the size expected from the summation of the individual inocula, or 0.03 cc. of mixed culture. Sulfadiazine effected an 88 per cent survival, sulfathiazole increased its effectiveness to an 80 per cent survival, and sulfanilamide gave a 48 per cent survival (Table 1).

A pilot experiment in which 7 dogs were treated prophylactically with penicillin against Cl. novyi produced a 71.4 per cent survival. The penicillin dosage, in this experiment, varied from 300 units to 2,000 units per kilo. It is probable that the lower dosage was inadequate.

## Therapeusis

Except for a pilot experiment in which penicillin was used against Cl. novyi, mixed inocula were the infectious agents used in the therapeutic phase of the work. For therapeusis with the sulfonamides, the sulfonamide-resistant Cl. novyi was omitted from the mixed inocula; otherwise, the mixed inocula included Cl. perfringens, Cl. septicum, Cl. sordellii, Cl. novyi, and Staph. aureus (Mixed Inoculum II).

In all the therapeutic experiments, inoculation was made at least three hours before treatment was initiated. In certain of the experiments this interval between inoculation and treatment was prolonged to six- and twelve-hour periods, with a resulting increase in the severity of the infection and in its resistance to the definitive agents.

\* Over a four- to five-year period 129 control dogs inoculated with Cl. perfringens yielded a 13.2 per cent survival. A total of 34 control dogs inoculated with Cl. sordellii gave a survival of 8.8 per cent.

**Definitive Agents**—The definitive agents for the therapeutic studies were sodium sulfadiazine, penicillin, and pentavalent gas gangrene antitoxin, or combinations of these drugs. In the antitoxin and penicillin experiments, sodium sulfadiazine was sometimes used as an auxiliary agent. The purpose of the auxiliary sulfadiazine was, first, to introduce a factor which would act directly on the invading organisms when antitoxin was the definitive agent, and, second, in order to simulate more closely battlefield conditions, where the wounded would have received prophylactic treatment with sulfonamides before reaching the base hospital for the definitive treatment.

**Dosage**—The dosage for penicillin therapy was established at a rather high level after lower dosages had proved unsatisfactory in the pilot experiments. The first two doses, given at a two-hour interval, were 2,000 units per kilo of body weight, the third through seventeenth doses were 1,000 units per kilo of body weight, and the eighteenth through the twenty-fourth doses were 600 units per kilo of body weight. In experiments in which the infection was allowed to progress for more than three hours before treatment, the 1,000 unit per kilo dose was maintained from the third through the final dose. The total penicillin dosage for a treatment, therefore, was either 23,200 units or 26,000 units per kilo of body weight.

The older method of administering gas gangrene antitoxin for curative treatment consists of administering an initial dose of four vials (each containing a "minimum therapeutic dose"), and three or four vials thereafter every four to six hours for two or three days. After preliminary

experimentation and consultation with various authorities in the field, massive doses of antitoxin over a short period of time were deemed preferable to the older method. The results obtained from subsequent experimentation upheld this opinion.

In a preliminary experiment the smaller and more extended antitoxin dosage was used, which was roughly 500 to 600 units of perfringens antitoxin per kilo with the other clostridial antitoxin units present in vial proportions. Eight doses of this strength were given at six-hour intervals for a curative treatment. The massive dosage of antitoxin agreed upon and used in all other experiments was 2,000 units per kilo of perfringens antitoxin, with the other antitoxins present in vial proportions. Four doses were administered, each at two-hour intervals, over an eight-hour period of treatment for a total of 8,000 units per kilo of body weight.

When used as a definitive agent, the therapeutic dosage of sulfadiazine was identical with that used in the prophylactic experiments. When used as an auxiliary agent, a single dose of sodium sulfadiazine was administered three hours after inoculation.

**Results**—With sodium sulfadiazine used singly as the therapeutic agent against the mixed infection of *Cl. perfringens*, *Cl. septicum*, *Cl. sordellii*, and *Staph. aureus*, there was a 48 per cent survival in a group of 25 dogs as compared to a 6 6 per cent survival in a control group. Against the same infection, using penicillin in a pilot experiment on 10 dogs, there was a 100 per cent survival (Table 2).

In a pilot experiment where penicillin was em-

ployed therapeutically against an infection produced by *Cl. novyi* alone, there was a survival of 66.6 per cent in a group of 6 dogs. However, part of the penicillin dosage in this experiment was lower than the dosage subsequently considered adequate. In all the above experiments, treatment was initiated *three hours after inoculation* with the infectious agents.

The infections for the remaining experiments in therapeutics were produced by the Mixed Inoculum II which included *Cl. novyi* as well as the organisms of the first mixture. A total of 99 control animals were used for this group of tests. At the same time controls were inoculated with single cultures of each of the organisms of the mixture, in order to check on any change in virulence of the individual species. There were no survivals in either the mixed or pure culture groups of controls.

Penicillin was used for therapeutics singly, with sodium sulfadiazine as the auxiliary agent, with sodium sulfadiazine as the second definitive agent, and with antitoxin as the second definitive agent. An experiment with penicillin used singly, *three hours after inoculation*, on 25 dogs, showed a 100 per cent survival. In an experiment with penicillin *six hours after inoculation* and with sodium sulfadiazine as an auxiliary, there was an 88 per cent survival in 25 dogs. In an experiment with penicillin *twelve hours after inoculation* and with sodium sulfadiazine as an auxiliary agent there was only an 8.3 per cent survival in 12 dogs. To check compatibility of penicillin and sulfadiazine, both agents were used definitively on 6 dogs, *three hours after inoculation*, with a resulting 100 per cent survival. In a second check, penicillin was used singly, *twelve hours after inoculation*, on 6 dogs, with no survivals.

In the experiment in which penicillin and antitoxin were used as joint definitive agents, treatment was concomitant with both drugs but was continued for only half the regular treatment period. Sodium sulfadiazine was used as an auxiliary agent and the definitive treatment was started *twelve hours after inoculation*. The survival in 25 dogs was 88 per cent. However, since two of the fatalities resulted from an anaphylactoid effect from the antitoxin rather than from the clostridial infection, the true percentage of dogs dying from actual infection was 4.4 per cent. This antitoxin-penicillin combination was apparently the best treatment for the advanced stages of the infection.

Pentavalent antitoxin was used for therapeutics singly, with sodium sulfadiazine as the second definitive agent, or with sodium sulfadiazine as an auxiliary agent. In the pilot experiment, antitoxin was administered in the smaller dosage over

a longer time interval and the results from this were unsatisfactory, since there was only a 62.5 per cent survival in 8 dogs, with treatment initiated *three hours after inoculation*. In an experiment in which the massive doses of antitoxin were administered, *three hours after inoculation*, over a short period of time (eight hours), there was an 88 per cent survival in 25 dogs. When antitoxin in massive doses plus sodium sulfadiazine as an auxiliary agent was administered, *twelve hours after inoculation*, a survival of 92 per cent in 25 dogs resulted (Table 2).

When antitoxin in massive doses with sodium sulfadiazine as the second definitive agent was used *twelve hours after inoculation*, a survival of 84 per cent in 25 dogs resulted. This percentage of survival, with sodium sulfadiazine administered throughout the experiment, is lower than the survival when only one dose of sodium sulfadiazine was given. However, the local sepsis with the extended sodium sulfadiazine treatment appeared somewhat less than when a single dose was employed.

### Statistical Analysis

The results of each of the experimental groups were tested by the chi square<sup>7</sup> technic against the corresponding control group results to determine whether or not the differences obtained could be attributed to chance. By this technic the hypothesis is set up that there is no difference between the results of the two groups being compared. From the survival results obtained in each of the two groups and in the total of the two groups, the survivals expected by chance were computed. The deviation of the obtained results from the expected results was then computed and chi square determined. The probability of obtaining a chi square as large or larger than that found was then looked up in the table of chi squares. The probabilities for each of the chi squares determined are shown in Table 1.

From the table, it may be observed that the differences between experimental animals and the controls are clearly not due to chance for all groups treated with sulfadiazine p ophylactically except the *Cl. novyi* group. The probabilities of obtaining chi squares as large as those occurring here were as small as  $2 \times 10^{-9}$ , so that we can reject with certainty the hypothesis that the differences arising between the controls and experimental groups are not real. Similarly, the animals treated with sulfathiazole showed higher survival rates than the control group. Again the differences cannot be attributed to chance except in the case of the *Cl. novyi*.

It should be noted that the survival rates are higher for the sulfadiazine-treated animals than for the animals treated with sulfathiazole.

The results for the sulfanilamide groups are not so conclusive. The probabilities are high enough so that we must retain the hypothesis that there is no difference in the case of the three inocula, *Cl. perfringens*, *Cl. novyi*, and *Cl. septicum*. For the *Cl. sordelli* and Mixed Inoculum I the probabilities are low enough so that we can reject with confidence the possibility that the differences are chance differences.

In the therapeutic studies all chi squares have low P values, indicating that there are real differences between the results of the experimental animals and those of the controls. The P values range from  $4 \times 10^{-4}$  to  $2 \times 10^{-9}$ .

### Clinical Applications

As pointed out earlier in this paper, clostridial infections, as produced by us in dogs are not entirely comparable to the clinical disease as it occurs in humans. The main difference is one of rapidity of progress of the disease, it being much more rapid and severe in the dog. Experimentally we see no cases of "clostridium cellulitis." All instances are those of true fulminating gas gangrene. As pointed out in a previous publication,<sup>2</sup> clinically one frequently sees mild, border line, and atypical cases which we have termed "clostridium cellulitis" in contradistinction to the fulminating case with deep muscle involvement.<sup>3</sup> In the dog we initiate the disease by introducing a large number of vegetative organisms and spores in conjunction with varying amounts of toxin. Clinically the individual has a variable number of spores introduced into the subcutaneous tissues by a variable traumatic mechanism. This injury may or may not be trivial and in itself may endanger the life of the individual.

Regardless of this particular aspect a certain and again variable length of time is required for the clostridial spores to become vegetative and proliferate. As proliferation progresses the exotoxins are formed *in situ*. It may require twelve to forty-eight hours after infection before the disease becomes manifest clinically. In the dog the disease, as produced by us, is clinically manifest in three to six hours. These differences must be kept clearly in mind when any attempt is made to transfer our experimental experience to clinical application.

**Prophylaxis**—We feel that from a prophylactic viewpoint sulfadiazine, given systemically in amounts sufficient to maintain an adequate blood level, is the best of the three sulfonamides employed, and sulfanilamide is the least effective. A high percentage of protection should be afforded against *Cl. perfringens*, *Cl. septicum*, and *Cl. sordelli*, provided sulfadiazine is given soon after injury and possible contamination

with any one of the three clostridial organisms named. If the contaminating organism should be *Cl. novyi* little or no protection can be expected from any one of the three sulfonamides employed.

In these studies we have not tested the relative efficacy of the sulfonamides when applied locally to the wound, and all our deductions are based on the systemic use of the drugs.

Penicillin was used prophylactically in a pilot experiment against *Cl. novyi* only. Here it was efficacious and would be expected to be. From a practical clinical viewpoint this biologic does not lend itself to prophylactic treatment and certainly could not be used routinely for this purpose under battle conditions. It is very rapidly excreted and it would be difficult to maintain an adequate blood level save with hospitalization. The limited supply and the high cost further contraindicate its use for such a purpose.

We have not tested the prophylactic use of pentavalent antitoxin in our studies.

**Therapeutics**—Once a true gas gangrene is clinically manifest, sulfadiazine, judging from our experiments, should be expected to be approximately 50 per cent effective. Here it may be best to give the initial dose in the form of sodium sulfadiazine intravenously in order to immediately obtain a therapeutic concentration of the drug in the blood. The clinician will have to use his judgment, the size of the dose depending upon the severity of the condition. Subsequent doses may be given by mouth, provided the patient is able to retain the drug and his condition is such as to permit adequate absorption from the gastro-intestinal tract.

Penicillin is much superior to sulfadiazine as a therapeutic agent and is also effective against *Cl. novyi* as well as the other three clostridial organisms employed. Early in the clinical disease it should be extremely efficacious against the disease, but becomes decreasingly so as toxicity progresses. In our studies a three hour postinoculation treatment resulted in a 100 per cent survival, treatment six hours postinoculation gave 88 per cent survival, treatment twelve hours after inoculation gave no survival (only twelve dogs were used in the last experiment).

This decreasing survival rate with increasing toxicity is to be expected. So far as we know, penicillin has no antitoxic properties. Late in the disease death may be and is caused by the exotoxins liberated by the invading organism even though the local sepsis is brought under control. This point should be kept in mind from the clinical standpoint. A patient or an animal may survive the infection and yet be left with permanent cardiac damage.

**Pentavalent Gas Gangrene Antitoxin**—Antitoxin, when given by the older method described

under the experimental studies, was not too effective (62.5 per cent of eight dogs) but when used in large amounts and given within eight hours it was very effective. In patients who are well advanced and toxic it is the only method we found effective. If supplemented by sulfadiazine (see Table 2) or penicillin it becomes very effective experimentally as late as twelve hours after inoculation. In using antitoxin clinically a predetermined dose is impossible. This can be determined only by the proper evaluation of the toxicity of the patient and the stage of the disease. The total amount should be administered within eight hours at intervals of not more than two hours. It should be remembered that antitoxin therapy is not without danger. Two of our dogs died an anaphylactoid death immediately following antitoxin treatment. Clinically the patient should be tested for sensitivity, and, if sensitive, carefully desensitized. Sulfadiazine or penicillin may be used during this desensitizing period. Experimentally, we found no contraindication to the combination of all three of these drugs. Preferably, penicillin and antitoxin should be combined in severe cases, the former to combat the local sepsis and the latter to neutralize the toxin.

The prophylactic and therapeutic measures which we have discussed should in no way interfere with the proper surgical care of the patient with gas gangrene, nor is it meant to replace adequate surgical care. We have previously pointed out<sup>2</sup> that surgical amputation should be dictated by the state of the vascular bed rather than by the infection. The presence of a relatively intact vascular bed leads to conservative measures.

## Summary

It should be borne in mind that this is an experimental study and any clinical recommendations made are based upon animal experimentation and previous publication of a clinical nature. Adequate surgical care should not be neglected. In the presence of an adequate circulation of the affected part conservatism should dictate the extent of surgical intervention. Often careful cleansing and adequate drainage will be sufficient surgery.

**Dr. John J. Morton, Rochester, New York.**—It goes without saying that adequate supportive measures are especially indicated in surgical infections.

It is my impression that the peritoneum is able to handle a considerable amount of infection, provided it is not a massive dose at one time or is not fed continuously from a focus. In the ordinary surgical infections, taken early, if the surgeon causes little trauma, healing will proceed without incident. The

Experimentally, sulfadiazine has proved to be extremely efficacious in its prophylactic use against *Cl. perfringens*, *Cl. septicum*, and *Cl. sordellii* infections in dogs when the disease is produced by individual pure cultures and when produced by a mixed culture of these same organisms contaminated by *Staph. aureus*. None of the sulfonamides were found to be effective against the disease when produced by *Cl. novyi*.

Therapeutically, sulfadiazine is far less effective but from our limited clinical use of this drug we have felt that it has been of value.

Experimentally, penicillin and pentavalent gas gangrene antitoxin are both powerful therapeutic agents. The latter is the more valuable of the two if used late in the disease, because of its toxin-neutralizing effect. It must be remembered that antitoxin must be used in large amounts and the entire dose given within a relatively few hours rather than spaced over one or more days. The possibility of an anaphylactoid reaction must be borne in mind when used clinically. The patient should be tested for sensitivity and, if he is sensitive, careful desensitization should be carried out. During the period of desensitization, sulfadiazine or penicillin should be used, preferably the latter, if it is available.

Experimentally we found no contraindication to combined therapy with any or all three of the agents discussed. Rather, they have an additive effect. It would seem reasonable in severe cases to give antitoxin in large amounts to control the toxic element, and penicillin for its effect upon the local sepsis.\*

\* We are indebted to Morey Jackson Wantman, assistant professor of education, University of Rochester, Rochester, New York, for the statistical analyses and interpretations.

## Discussion of Symposium

same is true for occasional accidental soiling. Care and gentle handling of tissues will pay dividends even in the presence of infection. It has been the experience in our clinic, reviewed by Sewell (in press), that the use of nonabsorbable suture material and avoidance of drains into or through the abdominal wall are also of importance. Some surgeons on the service are die-hards and have used catgut for years, so that we have had a number of acute

appendicitis cases to compare with a similar group in which silk or cotton has been used. Wound infections have been in the proportion of 2.4 per cent for silk or cotton to 9.7 per cent for catgut. This is almost a universal experience as recorded in the literature. When a silk-sutured wound does get infected, however, it usually takes 50 per cent longer in time to heal. In a series of simple acute appendicitis cases where no drainage was used subsequent wound infections were 5 per cent; with subcutaneous drains, 43 per cent; and with intraperitoneal drainage, 58 per cent. Intraperitoneal cultures were positive in 38 per cent of these cases. In a similar group of gangrenous appendicitis (in which 88 per cent of intraperitoneal cultures were positive) no drainage gave 29 per cent, subcutaneous drainage gave 72 per cent, and intraperitoneal drainage gave 100 per cent wound infection subsequently. In a group of 155 cases of perforation with gross contamination of the peritoneal cavity from 1936-1941, no drainage was used in 49 per cent, subsequent drainage was used in 52 per cent, intraperitoneal drainage was used in 40 per cent of wound infection, and subsequent pelvic and subphrenic abscesses and persistent peritonitis led to fatalities in the no-drainage group of 11.8 per cent, in the subcutaneous drainage group of 13.6 per cent, and in the intraperitoneal drainage group of 23.3 per cent. Some of us are convinced that catgut, being an absorbable material, causes a "wet wound" suitable for bacterial growth. The folds in a drain likewise trap serum to act as a focus for bacterial contamination. Consequently, by adopting nonabsorbable suture material and by using no drainage our results were improving.

With the advent of sulfonamides we used McBurney incision 100 per cent of the time, nonabsorbable sutures 96 per cent, no drainage 99.3 per cent, and sulfonamides in 97 per cent of the perforated cases (intraperitoneally and in the wound). This was followed by sulfa drug treatment in whatever way necessary. The results in 300 cases to July, 1943, were as follows:

Acute	232	2 wound infections	0.9%	No deaths
Gangrenous	31	1 wound infection	0.03%	No deaths
Perforation with peritonitis	33	11 wound infections	33.0%	1 death
Appendix abscess, catgut drains used	4	4 wound infections	100.0%	No deaths

This gives an over-all mortality of 0.3 per cent. We believe that we have lowered our mortality still further by the use of sulfonamides, and we have lessened the number and severity of the intra-abdominal abscesses. Saturation of tissues is important, but in the wound the sulfonamides slow healing. Therefore we gave up their use directly in the wound. When sulfa drugs are given intra-abdominally, 6-8 mg per cent can be recorded in the serum within twenty-four hours.

In regard to Major Carpenter's and Captain Mich's paper on the use of penicillin in patients with infected bone, our experience is meager. We have only had penicillin for use for a short time.

Our impression is that penicillin should be given intramuscularly and intravenously and probably also should be used directly in the wound. We have found that in so far as we have used penicillin, it has been necessary to remove sequestra when they have been present in order to get ultimate healing. It would be difficult to get a better series of osteomyelitis cases with any treatment than that reported by Dr. Robertson on osteomyelitis in children treated with sulfonamides. In our experience here, we have found that the most striking responses to penicillin have been in its use in serious cavities. Some remarkable results have been seen in meningitis, acute infections of the joints, and infections of the pleura observed in our clinic. It is absolutely essential to be sure that the bacteria are in the group responsive to penicillin therapy. It is our habit to test the organisms against the drug *in vitro* before using it on patients. It is well known that the *Escherichia coli* group of organisms neutralize the effects of penicillin. Consequently, penicillin is contraindicated with appendiceal perforation with peritonitis. It is to be hoped that the use of penicillin in bone infections will be thoroughly studied during the next year so that we will know what value it has in this type of disease.

As to anaerobic bacteria which Dr. Dowdy has reported on, I am in complete agreement with his observations. We have had a chance to follow this work over the last several years in which it has been going on. During this time gas gangrene has become rare in civilian life, possibly because of the use of sulfa drugs. There are several difficulties in the actual practice in the field. One is the difficulty in determining the exact type of anaerobic bacteria present. There are several groups, as Dr. Dowdy has brought out. For this reason we must have a sort of shotgun prescription to hit whichever organism might be the principal one. It is also important to separate out the clinical types of anaerobic infection. It is possible for the anaerobes to live in the subcutaneous tissue without doing any damage. I was able to culture them in the last war for long periods in what appeared to be clean wounds. It was possible to culture between the stitches and to grow *Bacillus welchii* in a surprising number. I have also been able to grow *B. welchii* from the brain and from the lung or pleura in many gunshot wounds in which no bad results followed. When a massive gangrene occurs with the shutting off of circulation and a heavy infection with anaerobic organisms, it would seem that sulfadiazine is the best of the sulfonamides and that penicillin is also excellent, and that polyvalent serum should also be used to neutralize the toxins which have been absorbed. In cases in which the circulation is gone, it will be necessary to amputate. In the less extensive types of infection in which there is merely segmental involvement in groups of muscles, treatment as indicated above will be successful in allowing the surgeon to save the limb and life of the individual.

It has been a pleasure to hear these papers of such timely interest to the profession. I wish to congratulate the speakers on their presentations and the surgical section for arranging this program.

# HISTORY OF A DRINKING HABIT IN 400 INMATES OF A PENAL INSTITUTION

With Special Consideration of Personality and Prognosis

PAUL WENGER, M.D., Plattsburg, New York

THIS study of 400 excessive alcoholics in a State prison was undertaken with full knowledge of the immensity and practical importance of the alcoholic problem. Drinking has become a world-wide social phenomenon which concerns physicians, psychologists, educators, ministers, and social workers. It has had its repercussions in the economic and political structure of this country, which has experienced a 'period of "prohibition," a subject of controversy right up to World War II.

In this paper the author will try, in addition to presenting the case study, to close some gaps in research, completed or under way, dealing with the scientific classification of a human habit which, in the opinion of this writer, reflects the precarious state of mind of modern man. In this respect addiction to intoxicants, especially alcohol, can be compared to the growing emotional instability and socially immature attitude among our contemporaries. All these phenomena represent social failures and will have their effect on the formation and type of postwar world which may signify for all mankind progress or retrogression, hope or despair.

Numerous authors have applied themselves to the problem of alcoholism. A. Forel, the late Swiss psychiatrist, and Haven Emerson,<sup>1</sup> in this country, have done pioneer work in this field. Besides, there exist several books or papers referring to or discussing the subject of alcohol and crime. Among these, W. Norwood East's<sup>2</sup> treatise in the *British Journal of Inebriety* of 1940, comprising a list of writings on the same subject, seems to be one of the latest and most interesting papers. The author, who points out that Britain has had the lowest European crime rate for the past decade, states, for example, that 19 per cent of England's murderers were chronic alcoholics, a figure which is close to that found by other authors. The paper also quotes various sources and authorities in England and other countries who believe that alcohol plays a definite role in 90 to 95 per cent of all crime and prostitution cases. In addition, he discusses the legal aspects of alcoholism—for example, the fact that, contrary to the situation in the United States, many European countries do grant extenuating circumstances to an offender who is found to have been even temporarily deprived of

his mental faculties. Another interesting fact is given by the author in establishing a 0.14 to 0.15 per cent concentration of alcohol in the blood as the demarcation line of intoxication, which means that such an amount of alcohol in the blood renders a person incapable of properly driving a car. As to treatment of criminal alcoholics, Norwood East considers psychotherapy as a helpful factor in their rehabilitation.

Of American authors, the Gluecks,<sup>3</sup> in their investigation of Massachusetts criminals, agree that from 40 to 60 per cent of their patients used alcoholic drinks excessively at some time or another. As to the mental effect of alcohol, I refer to a pamphlet issued by the New York State Liquor Authority<sup>4</sup> which gives an excellent description of the alcoholic frame of mind, mentioning expressly the tendency to trespass rules and conventions previously respected. More about physiologic and psychologic effects of alcohol on man can be found in Henderson and Gillespie's *Text Book of Psychiatry*. Finally, a paper by Thimann and Moore<sup>5</sup> entitled "Modern Scientific Treatment of the Chronic Alcoholic" was recently published which outlines all types and possibilities of treatment, pleading for long-term hospitalization of chronic alcoholics in order to adjust their personalities.

This study was compiled of specific material—namely, inmates of Clinton State Prison, New York, whom I had opportunity to observe and interview repeatedly throughout the summer of 1943.

According to available data secured from the inmates personally, and from other reports, the total population of 1,900 men at that time could be divided, as to their drinking habits prior to their arrest, into the following groups:

TABLE 1

Group	Number	Percentage
Temperates	646	34
Moderates	836	44
Intemperates	418	22
Total population	1,900	100

Roughly speaking, this would mean that one third of the prison population can be considered as abstaining, whereas two thirds indulged in alcoholic beverages prior to their arrest (one half of these were excessive drinkers). It would be

Senior clinical psychiatrist, Clinton Prison, New York.

interesting to compare these figures with the respective numbers computed out of the nonprison civilian population. Such statistics, unfortunately, are not available to the author at the present time.

Turning to the 418 intemperates—400 were selected and scrutinized in various ways. Their racial and social background, their physiologic and mental development were examined, the formation of their alcoholic habit was traced, the social implications of the habit were presented to them, and special consideration was given to their personality and prognosis. The following tables were compiled in accordance with such an outline. (Fractions of per cent were evened off, with the word "approximate" denoting this.)

### Racial and Social Background

Among the total prison population of 1 900 men at that time, the proportion of colored men to white was 20 per cent to 80 per cent. Of the 400 excessive drinkers 69, or approximately 17 per cent, were colored and 331, or approximately 83 per cent, were white men. This means that, relative to drinking, the white race had a slight edge over the colored, which, however, may prove negligible in a larger survey.

Table 2 shows the marital status of the selected cases.

TABLE 2

Status	Number	Percentage
Single	192	48
Separated or divorced	76	19
Married	74	18 (approximate)
Common law	35	9 (approximate)
Widowers	23	6 (approximate)
Total	400	

This table gives evidence of the wholesomeness of marital or at least common-law relations, whereas individuals who are single apparently take to drinking more readily.

Table 3 covers the occupations of our men.

TABLE 3

Occupation	Number	Percentage (Approximate)
Common laborers	177	44
Skilled laborers	162	41
Occupational drinkers (waiters, bartenders, brewers)	25	6
Professional and independent businessmen	25	6
Clerical workers	11	3
Total	400	

The table indicates that laborers indulge in drinking more than the clerical or professional group. However, the prison population consists

mainly of unskilled laborers, which proves again that social failure, like crime and addiction to alcohol, coincides with lack of vocational training, which is symbolic in socially useless personality types. The relatively low number of occupational drinkers would point to the assumption, expressed by some authors, that opportunity of obtaining drinks must not necessarily promote inebriety, but that in all probability personality and physiologic inclination play the decisive role in the formation of a drinking habit.

### Physical Development

Table 4 depicts the various age groups included in this survey.

TABLE 4

Age	Number	Percentage
10 to 19	1	
20 to 29	88	22
30 to 39	131	33 (approximate)
40 to 49	109	27 (approximate)
50 to 59	48	12
60 to 69	19	5 (approximate)
70 to 79	4	1
Total	400	

Thus it can be seen that excessive drinking affects younger persons up to the age of 40 (55 per cent) with a sharp rise in the age groups from 20 to 40. After the age of 40 it steadily declines.

Table 5 shows the physical (medical) classification of the 400 intemperates.

TABLE 5

Class	Number	Percentage (Approximate)
Class I (best condition)	67	17
Class II	273	68
Class III	38	10
Class IV (worst condition)	2	5
Total	400	

Most of the men are in class II, which denotes only fair health. Considering that the majority was in the younger age groups, it would indicate that excessive drinking has its ill effects on a person's health even if only to some degree.

Table 6 denotes the history of the men's social diseases.

TABLE 6

	Number	Percentage
History of venereal infections	160	40
No history of venereal disease	240	60
Total	400	

The percentage of the positive cases appears to be relatively high, this is another hint that

crime, addiction to intoxicants, and incapability to solve the sex problem are all manifestations of a social maladjustment.

### Mental Development

All 400 men were tested psychometrically in order to obtain their intelligence quotient (I.Q.).

TABLE 7

Status	I.Q.	Number	Percentage
Feeble-minded	Up to 70	3	1 (approximate)
Borderline	71 to 80	47	12 (approximate)
Dull	81 to 90	116	29
Average	91 to 110	181	45 (approximate)
Superior	110 and up	53	13 (approximate)
Total		400	

I.Q. of 100 = mental age of 15 years = normal intelligence.

The average and dull groups comprise the majority (74 per cent) of our men. In other words, excessive drinking seems to have had no effect on their intellectual capacities. This is understandable if one recalls that a majority—55 per cent (see Table 4)—were under 40 years of age and could not possibly have used alcohol for an appreciable length of time. It is known to psychiatrists that high-grade intellectual deterioration as a final outcome of a drinking habit usually requires more than a dozen years to materialize; it is a rather slow and gradual process. However, our findings should not deceive anybody as to the detrimental effect of habitual drinking on a person's social and moral standards.

Regarding the psychiatric classification of our material, the following data could be compiled:

TABLE 8

Status	Number	Percentage
Psychopathic	164	41
Alcoholic	116	29
Approximately normal	46	11 (approximate)
Potentially psychotic	35	9 (approximate)
Drug-addicted	23	6 (approximate)
Sex-perverted	11	3 (approximate)
Feeble-minded	3	1 (approximate)
Epileptic	2	
Total	400	

The table shows that only 11 per cent were classified as being approximately normal, although even these men partially showed either psychopathic traits or alcoholic trends, the latter meaning that there was an underlying inclination toward addiction to alcohol. The vast majority were psychopathic personalities of the antisocial, egocentric, or the more specific alcoholic, drug-addicted, sex-perverted, and epileptic types. In addition, approximately 1 per cent were considered as definitely feeble-minded, a negligible number, supporting the aforemen-

tioned statement that we are dealing with relatively young men, without the mental deterioration observed in cases of alcoholism of long duration. As to the drug addicts among the psychopaths, we could not find that drug addiction would bar completely a craving for alcoholic drinks. Such an assumption rests on a popular, but partly false, belief that "whiskey and drugs don't mix." The sex-perverted, among the psychopaths, form a relatively small group (3 per cent); they are nearly all homosexual or sodomists, but are not guilty of the more numerous cases of rape upon adult women. The so-called potentially psychotic cases (9 per cent) were emotionally highly unbalanced individuals, some of them on the brink of insanity.

Table 9 represents those having a history of insanity.

TABLE 9

	Number	Percentage (Approximate)
History of insanity	39	10
No history of insanity	361	90

Among the first group of 39 men who had been committed to a mental hospital one could find only 3 cases of a former alcoholic psychosis. In the great majority the hospital diagnosis was psychosis in psychopathic personality (periods of either excitement or depression). This, and the generally small number (10 per cent) of incidences of insanity among the excessive drinkers would strengthen the supposition of many leading psychiatrists that alcoholism is a symptom rather than a cause of mental disorders.

### Formation of the Alcoholic Habit

To trace the origin of the habit as to heredity, time of onset, physiologic inclination, type of preferred drink, and motivating factors formed one of the main reasons for this study.

As to hereditary factors, it is fairly safe to assume that chronic alcoholism has its noxious effects on the germ plasma. Extensive investigations have been made in this respect and we can find illustrative charts about these facts in every exhibition concerning health. Interestingly enough, our material shows the following somewhat surprising figures:

TABLE 10

History	Number	Percentage
Chronic alcoholism in one or both parents	155	39 (approximate)
No chronic alcoholism in parents	217	54 (approximate)
Unknown	28	7
Total	400	

Thus, a slight majority of parents were more or less abstainers, I say more or less, since this information was secured from convicts who, as a rule, are prone to prevaricate (Other data were supported by official investigations and reports) One may surmise that even the criminal is anxious to protect his parents' reputation. However, the apparent contradiction regarding these figures may be explicable if one views the average so-called "dead end kid" with his predilection for increased use of intoxicants.

The next table is interesting, as it shows the age at which drinking was started.

TABLE 11

Age	Number	Percentage
5 to 9	3	1 (approximate)
10 to 19	246	61 (approximate)
20 to 29	124	31
30 to 39	24	6
40 to 49	3	1 (approximate)
Total	400	

A majority began in their teens and 93 per cent were involved up to 30 years of age. Comparing this with the actual age of our men (see Table 4) one can roughly say that ten to twenty years elapsed from the onset of the habit until the individual found himself in the grip of the law. In other words, it still takes years until the steady use of alcohol leads to a loss of self-control to such an extent that major offenses are committed. Apparently there develops an internal struggle in a person between the good and bad character traits until the latter ones prevail, this is because alcohol physiologically lessens the control of the higher over the lower brain centers, thus impairing and finally eliminating sound judgment and common sense.

The physiologic inclination (taste) for intoxicants and especially alcoholic drinks is reflected in the following table.

TABLE 12

	Number	Percentage (Approximate)
Taste for alcohol	311	78
No taste for alcohol	89	22

It was authoritatively pointed out years ago that among the major causes of alcoholic addiction a taste for drinks might play an important role in establishing the habit. Our table would confirm this assumption, moreover, the real figures might be even higher on the affirmative side, considering the inmate's tendency to twist matters. Actually, this author believes that other physiologic factors besides taste act simultaneously toward formation of a drinking habit.

Apparently the whole gastrointestinal system must agree with the intoxicant, since it is known that ingestion of even small amounts of alcohol renders some people quite ill (vomiting, diarrhea, acidosis, etc). As pointed out previously, a relatively small percentage (6 per cent) of the men were classified as drug addicts, having used drugs and drinks conjointly prior to their arrest. Inquiring into a history of drug addiction, the percentage rose to 9 per cent, i.e., obviously our material was of the type which tends physiologically much more toward alcohol than toward drugs (alkaloids).

Table 13 gives evidence of the type of drink preferred by each of the men.

TABLE 13

	Number	Percentage
All types	216	54
Hard liquor	85	21 (approximate)
Beer	79	20 (approximate)
Wine	20	5

Thus a slight majority (54 per cent) used every type of alcoholic beverage. In general, a person with a long-standing alcoholic habit finds little difference between intoxicants as long as non-alcoholic beverages are excluded. Consequently, this group comprises the older men who had been victims of addiction for a long period of time. Drinkers of hard liquor, mainly whiskey, comprised the second largest group (21 per cent), beer drinkers closely following (20 per cent). Wine (5 per cent) seems to have been an unpopular beverage among our intemperates.

Finally, the formation of the habit with regard to the motives inducing a man to drink was examined.

TABLE 14

Motive	Number	Percentage
Sociability	302	76 (approximate)
Occupational opportunity	32	8
General worries	25	6 approx
Marital difficulties	23	6 approx
Inferiority feelings (anxiety)	18	4 approx
Total	400	

An overwhelming majority (76 per cent) made the acquittance of alcohol through their environment, specifically, at social occasions, such as house parties, or by frequenting saloons or so called beer gardens. The social factor constitutes the most potent incentive for drinking, out of the environmental influences in general. Sociability also played its part in the other groups. The occupational opportunity seems to have had relatively little effect as a motive, however, the number of occupational drinkers (see Table 3).

formed a small part of the total group, so that any definite conclusions in this respect would prove incorrect.\* Mental stress, in one way or another, as a motive for their habit, makes up for the remainder of our men. It is a fairly large group (16 per cent), out of which only 4 per cent claim anxiety as the moving cause. The role of anxiety in excessive drinking seems to be overestimated unless we consider all drinking as an expression of "timid souls." I shall revert to this point while discussing possible treatment of inebriates.

### Social Implications of the Habit

To engage in broad discussion as to the social implication of inebriety and its relation to crime appears to be superfluous, in view of the many excellent papers written on this subject. That chronic alcoholism accounts for family trouble and misery of all kinds is almost a truism, known to every child living in a slum district. In Henderson and Gillespie's *Text Book of Psychiatry*, drinking is regarded as the biggest single cause of crime. Perhaps the worst effect of alcohol on a man's mind is the evident gradual loss of judgment which leads to all sorts of abnormal—in many cases, antisocial—demoralizing behavior. An aggressive indecent attitude characterizes certain stages of intoxication which render a person incapable of controlling himself and make him liable to commit illegal acts. Such offenses may lead to long prison sentences; one third of our 400 offenders, for example, had to serve from ten to twenty years' imprisonment for crimes perpetrated while under the influence of intoxicating beverages.

The last of our tables depicts the range of crimes committed by our 400 inmates during a state of alcoholic intoxication. It is a clear admonition to all who are interested in public welfare and human progress in general.

TABLE 15

Type of Crime	Number	Percentage
Murder	46	60 { 11 (approximate) 5 32 (approximate)
Manslaughter	20	
Robbery	127	
Sex (rape, incest, bigamy, impairing morals of minor)	48	12
Acquisitive crimes (burglary, larceny, forgery, swindles)	148	37
Criminal negligence (fatal auto accidents)	8	2
Escape		
Abandonment	3	1 (approximate)
Arson		

We see plainly that the first four groups together (60 per cent) comprise the majority of crimes against persons, ranging from simple assaults to murder (11 per cent). Thus the violent

character of at least one half of all intemperates becomes manifest. The others (40 per cent) proved to be less active and restricted themselves to crimes of the acquisitive type. In general, the type of crime perpetrated seemed to be determined more by the man's personality than by external factors (environment, opportunity). Some of our inmates, especially those of the violent group (murderers, rapists), appear to be vicious creatures when intoxicated. It is this fact which impresses one mostly, to find a relatively pleasant, even shy, sometimes highly intelligent individual, who is accused of crimes completely out of proportion to his demeanor in a sober state of mind. Moreover, I doubt whether there is a more artful procurer to moral turpitude than alcohol. Most of the gross sex crimes can be traced back to alcoholic intoxication, since it is well known that alcohol acts as an aphrodisiac in many cases by abolishing sexual inhibitions, physiologically. Bewilderment during a state of intoxication leads occasionally to arson. Such offenders are registered, by psychiatrists mainly, as psychopathic personalities or hysterics, sometimes more specifically as pyromaniacs (propensity to incendiarism). Hardly ever is insurance money involved in these cases.

Among the more unusual crimes perpetrated by our excessive drinkers, a number of sex crimes (incest, attempted rape of old women, and murder of male friend) are interesting from the psychiatric angle.

### Case Reports

*Case 1.*—W. C. was a 20-year-old, single, white man of American parentage, the second born in a family of seven children, raised in a seaside section of Brooklyn, New York; his education continued through one year of high school. He worked as laborer; his I.Q. 123). He received excellent education in school but is considered by others as extremely sly and cunning. He received two suspended sentences for acquisitive offenses between the ages of 19 and 20; present crime, sex relations with 15-year-old sister (child born). The inmate is emotionally highly immature and was closely attached to this sister; together they visited beaches and places of entertainment. The inmate is now quite embarrassed about the matter, claiming that his sister did not understand the nature or effect of the crime; apparently there was no guidance of the girl. The striking point in this case is the contrast between the high intelligence and the low emotional level which resulted in moral depravation under the influence of liquor. . . . does not prevent a person . . . morally—a fact which . . . d by the public.

*Case 2.*—H. G. was a 48-year-old white man of German parentage, the third among eleven siblings. He had a criminal record from the age of 23 for acquisitive as well as sex crimes. He assaulted a 60-year-old spinster in a cemetery; he does not recall anything about it, because of his intoxication

at the time. He was charged with another similar attack in a cemetery. One of his brothers has a long criminal record. The inmate was employed as a weaver and also was sentenced as a deserter from the United States Army; he patronized prostitutes, but denies being "oversexed." The patient's intelligence is in the dull level (I.Q. 83). He is considered by psychiatrists to be a psychopathic personality; he is seclusive and an introvert, except when under the influence of alcohol. The outstanding feature of this case is the patient's abnormal sex life. He appears to be shy when sober, but becomes aggressive when intoxicated and apparently stalks his victims in hidden places. Alcohol helped him to overcome his otherwise cowardly attitude toward the love problem, rendering him superior to old women and children.

Case 8.—A. O. was a 56-year-old, single, homosexual Negro; he was the only boy in the family, and had three sisters. His occupation was given as

suave, whimsical attitude, with pronounced effeminate manners. Particularly interesting is his

becoming bored with girls, who, he claims are nauseating. The inmate asserts that he would not have lost his composure had he not been drinking. Again, we see that intoxicants support this man's abnormal will for power, expressed in his violent fits of jealousy.

This study attempts to examine all factors contributing to the formation of a drinking habit. But with all consideration given to environmental influences, one sees repeatedly that the personality of the alcoholic plays a decisive part in the total course of his life and destiny, determining also the recurrent type of his antisocial conduct. The mental development of the inebriate, his motivation for starting the habit, the unfavorable social implications of such an addiction—all these factors point to what may be condensed into one word: personality. Without doubt, conscious and unconscious feelings of inferiority or insecurity, natural and normal in adolescence, cause a person to seek contact with others to unburden himself from all the pressing problems of life. The kind of entertainment and sociability will then determine whether such a person is initiated into a drinking habit. Whether he continues drinking will depend not only on his environment (opportunity, occupation) but apparently to a large degree on his state of mind (personality), supported by a physiologic inclination (taste, etc.) for alcohol.

It was interesting to divide our 400 cases into a few groups according to their personalities and the special character traits ascribed to chronic al-

coholics, such as emotional instability, anxiety, etc. The following table shows the result:

TABLE 10

	Number	Percentage
Extroverted, sociable and cooperative	252	63
Introverted, unstable, anxious	98	24
Aggressive	28	7
Religious	20	5
Jealous	4	1

Thus, a fairly large majority (63 per cent) were found to be relatively sociable and cooperative but apparently took to drinking, feeling unable to face the usual responsibilities and problems of life. A relatively small group (24 per cent) evinced signs of a neurotic attitude promoted by personal worries and anxiety, such as marital difficulties or sickness. That the group of those who are decidedly aggressive comprises only 7 per cent of the total intemperates will not surprise anyone who recalls the rule that addicts in general are less active than other social misfits. The small group (5 per cent) of the devoutly religious men was found to be very similar in their general make up to the introverts. The negligible group of those professing jealousy was not regarded as revealing the true figure of such individuals; obviously, a convict prefers to be taken as "tough," which in itself is not consistent with too much concern shown over his partner's attitude. A more detailed personality study of the occupational drinkers was not contemplated in this paper, since the number of such cases was insufficient to be used convincingly. Altogether, no outstanding character features were discovered among our excessive drinkers except for the fact that their personalities reflected the underlying, and, for the most part, unconscious, feelings of inadequacy in dealing with life's problems. In this respect, drinking must be considered as a trick to rid oneself of such feelings.

It is fitting, after scrutinizing our material in various directions, to look for the practical value of this study. What can be done to prevent crimes committed after drinking sprees? Will these 400 men relapse into their habit after release from prison? Can they be treated and cured of their addiction? Obviously, something has been done in our cases, since it was pointed out that their personalities did not evince such repulsive characteristics as are usually seen in intoxicated persons. Apparently enforced abstinence in the institution had its wholesome effect. It may not have altered their basically "timid souls," but it has been a prerequisite for any other successful treatment, be it medical, mental, or spiritual. If they are guided after dis-

charge in a scientifically planned way and thus acquire the ability to lead a social life with an adequate emotional outlet, their prognosis can be considered as favorable. To prevent crimes perpetrated in a state of mental confusion caused by alcohol, we must remain alert and aware of the fact that habitual drinking, whether moderate or excessive, represents a mental crutch for persons who lack social and emotional maturity. If we can instill a broader, more intensive social interest into the minds and hearts of the younger generation, we shall have accomplished a major achievement toward crime prevention both in inebriates and in abstinents.

## Conclusion

Four hundred former excessive drinkers, con-

fined in a penal institution, have been scrutinized with regard to their background, their personal development, and the formation of their habit. The role of personality as the decisive factor in their social failure was illustrated. Possibilities of treatment and prevention of inebriety were advanced.

## INTERNATIONAL COLLEGE OF SURGEONS MEETING

The program at the Ninth Annual Assembly of the United States Chapter of the International College of Surgeons will be devoted to war, rehabilitation, and civilian surgery. The sessions will be held at the Benjamin Franklin Hotel in the City of Philadelphia, October 3, 4, 5, 1944.

The convention will open at 10:00 A.M. on Tuesday, October 3, with an address by the Honorable Bernard Samuel, Mayor of the City of Philadelphia, to be followed by Dr. Rufus S. Reeves, M.D., Director of Public Health, Philadelphia, Hubley R. Owen, M.D., president of the Philadelphia Academy of Surgery, and Charles L. Brown, M.D., president of the Philadelphia County Medical Society.

In the evening "Service Night," the guest speakers will be Vice-Admiral Ross T. McIntire (MC), U.S. Navy; Maj. Gen. George F. Lull, Deputy Surgeon General, U.S. Army; Captain Joel J. White (MC), U.S. Army, Dr. Charles M. Griffith, Medical Director, U.S. Veterans Administration, and other distinguished guests.

Dr. Morris Fishbein will be the principal speaker at the convocation exercises on the following evening, when one of the largest classes in the history of the College will be accepted into Fellowship and Membership. Dr. Rudolph Jaeger, formerly of Denver, Colorado, and now in charge of neurosurgery at Jefferson Hospital, Philadelphia, will be inducted into office as the new president of the United States Chapter of the College.

Among the activities planned are a tour of hospitals and attendance at clinics, under the direction of Dr. Leonard D. Frescoln, of Philadelphia. More than fifty prominent surgeons and others engaged in the work of rehabilitation and occupational therapy will present twenty-minute papers during the morning and afternoon sessions.

There will be general surgery in one group and alternating groups of gynecology and ear, nose and throat.

More than 250 feet of panel space has been set aside for scientific exhibits, some of which are being shown at this Assembly for the first time. Among these exhibits are "Thyroid Surgery Demonstrating a New Triangle for the Localization of Recurrent Laryngeal Nerve on the Basis of new Landmarks," "Neurosurgery," "Surgical Treatment of Cancer

of the Rectum Without Colostomy and Preservation of the Sphincter Muscles," "Sclerotherapy," and many others.

Among some of the special features to be shown are a new exhibit on war activities by the American Red Cross and the original paintings "The Seven Ages of the Physician," through the courtesy of the Ciba Pharmaceutical Products, Inc., and "Pioneers of Medicine" through the courtesy of Wyeth, Incorporated.

A variety of motion pictures in black and white and in color will be shown on craniocerebral surgery, bone and joint surgery, plastic surgery, as well as some new and original pictures dealing with medical entities.

Special arrangements have been made with hotels in Philadelphia to take care of visitors from distant places. Information may be secured from Dr. Benjamin Shuster, Philadelphia.

The medical profession is invited to attend the Assembly and its sessions.

Physicians from the New York area who will speak at the sessions are: Dr. Frederick M. Allen, professor of internal medicine, Polyclinic Hospital—"Surgical Shock and Its Treatment"; Dr. William Seaman Bainbridge, consulting surgeon, Third Naval District, and Attending Specialist in Surgery, U.S. Public Health Service—"A Survey of Surgical Results in Cancer"; Dr. A. A. Berg, consulting physician, Mt. Sinai Hospital—"The Preservation of the Sphincter Ani in Radical Operation for Cancer of the Rectum"; Dr. Lyman Weeks Crossman, professor of clinical surgery, New York Medical College—"Refrigeration for the Preservation of Traumatized Tissue"; Dr. Elias D. Lawrence, adjunct surgeon, Bernert Hospital, Paterson, New Jersey—"Saphenous Vein Ligation"; Dr. Oswald Swinney Lowsley, past-president, American Urological Association—"Plastic Operations Upon the Kidneys"; Dr. Frances I. Seymour, medical director, National Research Foundation for the Eugenic Alleviation of Sterility—"The Responsibility of the Surgeon in the Preservation of Human Fertility"; Dr. Asher Winkelstein, chief, Gastrointestinal Clinic, Mt. Sinai Hospital—"The Relation of Gastric Acidity to Recurrent Ulcers After Partial Gastrectomy."

# VOICE AND BREATHING DISABILITIES FOLLOWING THYROID SURGERY

CHAS GORDON HEYD, M D , D M Sc , F A C S , New York City

NO CLINIC and no surgeon have been immune from voice and breathing disabilities following thyroid surgery. Injury to the breathing and vocal functions of the larynx following thyroid surgery varies from slight, unrecognized, and spontaneously ameliorated conditions to the tragic and devastating results of bilateral abductor paralysis.

It has long been recognized that a patient, after a thyroid operation, may have a unilateral abductor paralysis and exhibit no symptoms or disability thereafter. The maintenance of abductor function on the other side, with subsequent compensation for phonation, is sufficient to insure normal voice, normal breathing, and preservation of the sensory mechanism of the larynx. It is a matter of surprise to most thyroid surgeons to learn, during the course of their experience, of the number of individuals with goiter who have unilateral vocal cord paralysis and who have never been operated upon for their goiter.

When a vocal cord loses its function by a slow and continuous pressure, such as occurs in a progressively enlarging nodular goiter, there is ample time for compensation to take place. Compensation, however, takes time. This condition is essentially different from that which occurs as the result of an anatomic division of the nerve. Compensation in the latter instance cannot be acquired quickly. According to Hoover<sup>1</sup> there is hoarseness or loss of voice immediately following the section of one recurrent laryngeal nerve with the loss of function of this one cord. Ordinarily, however, the loss of function of one cord results in a temporary loss of voice, which lasts from a few days to several months, but one can say almost certainly that the loss of one recurrent nerve will not result in any discomfort to the patient as far as respiration is concerned, and we can assure the patient that the voice will return, because the cord will eventually come to the midline.

The reports of numerous observers and some experimental evidence suggest that undue traction or rough manipulation of the thyroid will not of itself produce injury to the recurrent laryngeal nerve. Yet it has been my experience on numerous occasions, during the course of a subtotal thyroid resection that a patient who is having uniformly smooth respiration—without

any inspiratory or expiratory sound—will develop suddenly an inspiratory stridor upon traction of either the superior or inferior pole of the thyroid. So impressive is this change in the orderly and normal noiseless breathing that it has been a surgical axiom to desist from operative procedures in the area that produced the changed breathing and to proceed with the resection from another approach. I have always viewed a change from noiseless, quiet respiration to a stridulous inspiration as one fraught with danger in regard to laryngeal function after the operation. I am convinced that traction is a dangerous procedure, especially if mobilization of the thyroid is carried out from below upward, and particularly in substernal goiters. There certainly must be a limit to the amount of stretching the recurrent laryngeal nerve may receive without having physiologic loss of function.

Some rather bizarre laryngoscopic findings have been recorded.<sup>2</sup> Paralysis of the vocal cord on the side other than where the goiter is situated, and paralysis of the vocal cord on the side with the least gross tumor or mass are examples. It is not a uniform practice to examine the larynx of every patient with a goiter, but when a competent laryngologist has examined every patient one is surprised to learn that approximately 10 per cent of goiterous patients have a one-sided vocal-cord paralysis before operation. It is unfortunate statistically, that every patient with a thyroid condition has not had a postoperative examination of the larynx. It is alleged that approximately 15 to 20 per cent of the patients operated upon for goiter have, at some time postoperatively, some disability of the vocal cords. Happily, most of these resolved during the immediate postoperative hospitalization or shortly thereafter. However, one would judge from an examination of the literature that about 3 per cent have permanent vocal cord disability in varying degree, and about 1 to 1.5 per cent have major cord disability on both sides following thyroid surgery.

It is a rather interesting observation that it is not the largest goiter preoperatively that produces the greatest number of voice disabilities. In fact, preoperative cord paralysis is found in patients with relatively moderate-sized goiters. One would anticipate that large, nodular, intrathoracic goiters, with displacement and compression of the trachea, would rate high in the numerical frequency of cord disabilities. Such,

Read before the Southern Surgical Association, New Orleans, Louisiana, December 7-9, 1943.  
From the Department of Surgery, New York Post Graduate Medical School and Hospital.

however, is not the case, for with the continuous enlargement of the nodular goiter the trachea and the nerve are displaced and stretching of the nerve—if it does occur—is brought about so gradually as not to produce a high frequency of vocal cord change.

The larynx has three functions,<sup>3</sup> all closely interdependent and each necessary for normal voice and respiration. First, and foremost in importance, is the preservation of a normal respiratory airway. This presupposes a normal innervation and a normal muscular apparatus of the larynx. Second is the maintenance of the inspiratory reflex. This function is necessary to protect the larynx from the entrance of foreign bodies, such as food particles and fluids. Third is the preservation of voice. In order for normal voice function to be maintained it is necessary that all of the intrinsic muscles of the larynx function in perfect unison, and with normal innervation.

The disabilities of the voice and breathing in connection with thyroid surgery vary from slight to tragic. We may list them in order of severity somewhat as follows: (1) spasmodic episodes of painful coughing with no expectoration; (2) mucus retention with inability to clear the throat; (3) pain over the region of the molar teeth—the thyromandibular reflex—and the occasional ear-ache; (4) the spasmodic spilling over of fluids into the larynx; (5) the normal voice but with early fatigue and hoarseness; (6) change in the pitch of the voice; (7) the hoarse voice at all times; (8) the inspirational stridor; (9) the stridor and crooning noise when asleep; (10) the whispered voice at all times; (11) dyspnea on exertion; (12) dyspnea on the slightest exertion; and (13) dyspnea at rest.

It is a formidable array, and the interpretation of many of these complications is still doubtful. We know that the superior laryngeal nerve concerns itself with: (1) sensitivity of the upper respiratory or laryngeal mucosa; (2) the innervation of the interarytenoid muscle; and (3) the innervation of the cricothyroid muscle. We know that the recurrent laryngeal nerve supplies all of the intrinsic muscles of the larynx except the interarytenoid muscle and that a total bilateral injury of the recurrent laryngeal nerve means a paralysis of all of the intrinsic muscles of the larynx, that is, the abductors, the adductors, and the intrinsic tensor muscle.<sup>4</sup> Twenty-three years ago, before this Association, the late Dr. E. S. Judd<sup>5</sup> drew attention to the marked variation in the fibers of the recurrent laryngeal nerve. The major function of the larynx is preservation of the airways. This process is an automatic one and is brought about through the activity of the abductor fibers. Phonation is a voluntary function. We have, therefore, a single nerve trunk

carrying continuous automatic impulses, side by side with fibers carrying interrupted or voluntary functions. Experience suggests that the abductor fibers (involuntary) are more easily injured and degenerate sooner than the fibers that carry voluntary impulses.

It is somewhat presumptuous on the part of the general surgeon to attempt to interpret the many bizarre combinations of respiratory and voice changes incident to surgery of the thyroid. It is evident that there is a high compensatory mechanism in the larynx, both for respiration and phonation, and there is considerable variation in the distribution of both the superior and recurrent laryngeal nerve. Little recognition has been given to the fact that there is an anastomosis—nerve of Galen<sup>6</sup>—between the superior and inferior laryngeal nerves. It is this anastomotic bypath that allows compensatory innervation when the recurrent laryngeal nerve is severed. Again, it has been demonstrated frequently that there is an extralaryngeal division of the recurrent laryngeal nerves in fully two-thirds of all individuals. In Lahey's article "Routine Dissection and Demonstration of Recurrent Laryngeal Nerve in Subtotal Thyroidectomy"<sup>7</sup> one reads: "Note its (recurrent laryngeal) division in the two branches, one larger than the other . . . this is an extralaryngeal separation of the nerves into segments to supply the abductors. We have repeatedly seen these extralaryngeal divisions in the course of our operative dissection of this nerve." Later in the text one notes: "In an occasional case the nerve may split into the relatively large group of fibers innervating the adductor muscles of the cord, the crico-arytenoideus lateralis, and the relatively small group of fibers innervating the abductor of the cords, the crico-arytenoideus posterior."

It would appear that the fibers that supply the abductor muscles of the larynx are more susceptible to trauma than those that supply the muscles of phonation. It is not unusual post-operatively to find, on laryngeal examination, that there is a sluggish cord but one with movement which causes no interference with the breathing aperture and with relatively normal phonation.

Of fundamental importance in the consideration of voice and breathing disabilities is an anatomic knowledge of the intrinsic muscles of the larynx and their innervation.<sup>8</sup> The recurrent laryngeal nerve supplies all of the intrinsic muscles of the larynx, both the abductor and the adductor, except the interarytenoid. The recurrent laryngeal nerve carries in separate fasciculi fibers controlling the abductor muscles—the cricoarytenoideus posterior—and fibers controlling the adductor muscles—the thyro-aryte-

noideus, the thyro-arytenoideus lateralis, and the crico-arytenoideus lateralis. The interarytenoid however, is supplied by the internal branch of the superior laryngeal nerve.<sup>9</sup>

The superior laryngeal nerve, represented by an internal and an external branch, has a highly important function in the maintenance of normal laryngeal function. The purpose and function of the superior laryngeal nerve have been largely overlooked by goiter surgeons. The internal branch of the superior laryngeal nerve is concerned with the preservation of laryngeal tone and innervates the interarytenoid, while the external branch supplies only the cricothyroid—a muscle which depresses the thyroid cartilage and acts as a tensor to the vocal cords. The internal branch of the superior laryngeal nerve passes through the thyrohyoid membrane very close to the superior pole of the thyroid and many times is injured in mass ligation of the superior pole, resulting in the surgeon's being somewhat surprised when the patient, immediately postoperatively has violent attacks of coughing and complains that on swallowing material enters the larynx.

We have been told that after severe injury to the recurrent laryngeal nerves the better the voice the g . . . s the voice . . . ”

The worse the voice, the surgeon says, the better will be the breathing space. Anatomic studies prove that the interarytenoid muscle is innervated solely by the internal branch of the superior laryngeal. This explains one of the catastrophes of goiter surgery, for with a loss of the abductor function the cords would naturally tend to approximate each other in the midline, and if the internal branch of the superior laryngeal was not injured the interarytenoids would certainly close the posterior third of the glottal aperture, thus giving a fairly good voice but only a “chink” aperture for breathing.

The cricothyroid muscle has two sets of fibers—the vertical and the oblique. Its purpose is to tense the vocal cords—one of the primary functions of phonation. It is innervated by the external branch of the superior laryngeal. Injury to the main trunk of the superior laryngeal will bring about a paralysis of the cricothyroid muscle and the interarytenoid, and, assuming that the recurrent laryngeal nerves are intact, the vocal cords would be in approximation throughout the anterior two thirds but with a triangular space at the posterior one-third, thus allowing adequate air space but causing practical aphonia.

If the external branch of the superior laryngeal were injured the cricothyroid muscle would be paralyzed and would account for the hoarse-

ness which comes on after using the voice for some time.

A voice disability that has serious significance and which is readily corrected presented itself in a patient who had a subtotal resection and immediately after the operation had normal breathing and normal voice.<sup>10</sup> The operative wound had been closed without drainage. Within a few hours, two or three at the most, the patient began to develop a definitely brassy, metallic voice and breathing became very difficult. This condition progressed with increasing severity and the inspiratory difficulty became more and more marked. In a case of this type there has been no injury to the nervous mechanism of the larynx, but there has been an accumulation of a small amount of blood or wound serum within the fossae formerly occupied by the lobes of the thyroid. These fossae roofed over with the sutured ribbon muscles, offer a cul de sac for the accumulation of fluid with direct pressure on both recurrent laryngeal nerves. Once one has witnessed this complication, its correction is relatively easy. The clips are removed from the skin incision, the skin flaps are raised, and a small amount of picking is introduced to keep the skin flaps elevated. After an hour the sutures that bind the muscles together are cut, the muscle flaps are gently lifted up, and into the space some sterile gauze is lightly inserted. The decompression of the thyroidal fossae lessens the pressure and, slowly but surely, the respiratory symptoms disappear and the voice loses its brassy and metallic quality. At the end of twenty-four to thirty-six hours the patient becomes practically normal so far as the larynx is concerned, and in a few days the wound is closed by secondary suture, with almost the same cosmetic effect as after a primary operation.

One of the annoying complications, but with it not dangerous, nor in our opinion does it lead to subsequent vocal disturbances of major importance, is the development of a postoperative tracheitis. It would appear that in every case of subtotal resection there is some postoperative edema of the mucous membrane of the larynx and upper trachea, and this edema would interfere with the normal laryngeal tonus as is evident by the pain on swallowing and the loss of a prompt cough reflex, resulting in the spilling of fluids into the larynx. Uniformly, this complication appears about twenty-four to thirty-six hours after the operation in a patient who has had a normal voice and normal breathing immediately after operation. The voice becomes hoarse but without a brassy or metallic quality. Under rest and sedation the condition clears up and the symptoms entirely disappear.

Not to be lost sight of in the consideration of

this problem is the patient who has an almost pathologic loquaciousness. This type of patient, three or four days after a thyroid resection, when swallowing is somewhat painful, develops a falsetto voice from overuse and straining. On laryngologic examination the cords move sluggishly. After his discharge from the hospital he persists in straining his voice, so that eventually his cords present the picture of a chronic laryngitis from fatigue. It has been necessary to place two of these patients in charge of a teacher of voice control, and the results have been surprisingly good. By a process of re-education in voice placement and rest they lose the falsetto quality and have a relatively normal voice.

Two schools of thought have arisen in regard to the technical procedures in thyroid surgery as it concerns the recurrent laryngeal nerve. There are two advocates, one of the chief proponents being Lahey,<sup>22</sup> who advise anatomic exposure of the recurrent laryngeal nerve in every thyroid resection. Their position is predicated upon the following observations: (1) that the nerve possesses an almost uniform contour of anatomic line; (2) that it may be readily identified by vision and palpation; (3) that it is always in relation to the branches of the inferior thyroid artery; (4) that only by anatomic exposure and complete visualization throughout the course of the thyroid resection can the surgeon be assured that no operative trauma will happen to the nerve; (5) that sometimes the nerve actually passes through the thyroid tissue and that the assumption "if the clamps bite into the thyroid tissue, the nerve cannot be injured" is not tenable; and (6) that the nerve, if and when injured operatively, is injured close to its point of disappearance under the lower border of the inferior constrictor muscles, and that it is just in this area that the thyroid is most densely attached to the lateral surface of the trachea, so that any attempt to control a bleeding vessel in this situation without actual visualization of the nerve is liable to injure the recurrent laryngeal nerve.

The other school of thought is championed by Dinsmore, who states: "The less I see of the nerve the better I like it." The reasons advanced for his position are: (1) that if the clamps are applied to thyroid tissue and the resection is carried out above the clamps the nerve will not be injured; (2) that visualization and anatomic dissection of the recurrent laryngeal nerve, by and of itself, produce trauma to the nerves; (3) that the syndrome of abductor paralysis can occur after thyroid surgery without any operative injury to the nerve; (4) that the nerve is not an inherently strong nerve and is susceptible to degeneration from the mere operative intervention and handling; and (5) that cicatrization

around the nerve is an important factor in nerve disability.

Clinically, laryngeal disability following thyroid surgery may express itself in many diverse forms:

1. Disabilities that arise during the course of the operation. Under ordinary circumstances and with good anesthesia, the breathing of the goiter patient, aside from those having respiratory difficulties from massive goiters, should be smooth, and without any inspiratory stridor. During the course of the operation many patients do have some vocal change at some point in the resection. This may manifest itself by a change in the expiratory "grunt," but the development of an inspiratory stridor during the course of an operation is a danger signal, and all manipulation should be terminated until breathing becomes normal. It has been assumed, and I think correctly, that any interference during the course of an operation with the function of the recurrent laryngeal nerve will manifest itself by some degree of inspiratory stridor. This is denied by some surgeons, who maintain that the recurrent laryngeal nerve may be injured on one side during an operation without causing any audible change whatsoever. It is for this reason that some operators have insisted upon using local anesthesia so that the patient could phonate or talk during the operation. Bilateral abductor paralysis has occurred in the experience of surgeons who use local anesthesia exclusively.

I think it is correct to maintain that the severance of the recurrent laryngeal nerve during operation will be accompanied by marked inspiratory stridor and by great difficulty in inspiration. Whether a pinch on one side of the nerve without severance will produce any declarative changes in respiration and voice sounds is still not settled. It would appear, however, that after such an injury, degeneration takes place and later comes the tragedy of the "chink" glottis.

2. Patients may have laryngeal dysfunction postoperatively and during hospital residence. For some reasons not thoroughly understood, some patients are returned to bed after a goiter operation and have respiratory difficulty, with changes in voice. They are blue and have difficulty in swallowing fluids, but after a few days the protective mechanism of laryngeal tone is re-established, and they swallow without difficulty and the voice improves. The surgeon is happy that the patient is recovering from some laryngeal disability caused by a temporary mechanism. The patient is discharged from the hospital with a fair voice and adequate breathing airway. Some of these patients will have a complete recovery, but a few, unfortunately, will

come back in not less than six months with only a slight laryngeal fissure for airway. The voice will be fairly good, although a little husky in its lower ranges, and yet they will be in manifest difficulty by reason of their narrow "chink" glottis.

3 Another group of patients are those who return from the operating room and on the first spoken words have a normal voice and no respiratory difficulties. The color is excellent. At the end of forty-eight to seventy-two hours they have attacks of coughing, lose their voice, have some "spill over" of fluids. After a relatively short time they regain their voice and their laryngeal tone, and have no difficulty with breathing. These cases probably represent temporary reactive changes in the larynx sequential to operative trauma.

We have been greatly impressed by the work of one of our associates in the Thyroid Clinic at the New York Post-Graduate Hospital. Dr. Charles O. Fiertz,<sup>12</sup> in "an experience with some 30 cases of vocal cord paralysis, has shown that the great majority of vocal cord disabilities following thyroidectomy are not due to actual severance of the nerve but rather to a more or less severe traumatism and, therefore, are reversible if biologic therapy is instituted. This consists of a steady cathode galvanization over the nerve and interrupted muscle stimulation over the laryngeal muscles of the affected side by whichever current is needed for a good contraction of the vocal cords. In the presence of partial reaction of degeneration—the faradic current, in the absence of faradic response—the galvanic current should be employed. The patient is treated on the basis outlined above for six to eight weeks. If re-examination at that time reveals no change, an anatomic block has to be assumed, and further therapy is useless. If the original examination shows that some faradic response is preserved, the outlook is excellent and restitution within three months can be expected."

The results obtained by Fiertz with this treatment have been surprising, even when the prognosis at first examination was extremely dubious.

By way of illustration, a case of one of Fiertz's patients is herewith reported. It is neither the worst nor the best of his cases. It does, how-

ever, indicate what may be done by patient and persistent effort.

### Case Report

T. R., a woman of 32, consulted Heyd in March 1934, complaining of nervousness, palpitation, and "whisper voice"; she had an indwelling tracheotomy tube. Early in May, 1933, she was treated elsewhere with roentgen ray for hyperthyroidism and on May 29, 1933, an emergency low tracheotomy was performed for "bilateral vocal cord paralysis." The patient was admitted to the Post-Graduate Hospital in April, 1934, and a study was made of her condition. It was found that she had a bilateral abductor paralysis and a basal metabolic rate of +37. On April 21, 1934, the patient had a subtotal thyroid resection of the right lobe, and on May 2, 1934, a subtotal resection of the left lobe of the thyroid. After the second stage the patient was aphonic for four days, when the voice improved. At all times the tracheotomy tube was left in place. The hyperthyroidism was successfully corrected by these two operations. The tissue removed was reported as "hyperplastic thyroid, Graves' disease type, with chronic thyroiditis." In February, 1935, dilatation of the larynx was attempted with no benefit. On October 18, 1940, re-examination of the larynx revealed "both cords paralyzed." On October 29, 1940, Fiertz began electrotherapy and on December 6, 1940, laryngoscopic examination revealed that "the right cord moves on galvanic and faradic stimulation." On February 3, 1941, both cords were moving and the tracheotomy tube was removed. The patient received thirty-seven electrical treatments between October 22, 1940, and January 31, 1941. In brief, this patient had a bilateral abductor paralysis before any surgery was performed. After seven years electrotherapy was instituted. Vocal and breathing disability was corrected and the tracheotomy tube was removed.

### SEVEN ELECTED TO MENTAL HYGIENE GROUP

Dr. George S. Stevenson, medical director of the National Committee for Mental Hygiene, has

man of the American Red Cross. Other new members include Dr. Lauretta Bender,

psychiatrist at P. Gayle, Jr., of Social Security, Kubie of the N. Hygiene, Dr. Thomas A. C. Rennie of Cornell University, and Miss Mildred C. Scoville of the Commonwealth Fund.

# HUMAN TOOTH INJURIES

OTHO C. HUDSON, M.D., Hempstead, New York

THE question of a human bite is of enough importance to stress the value of educating the public on early and adequate treatment and to refresh the minds of the doctors on the end results of untreated and maltreated cases.

Cauterization as treatment of animal bites is well known. However, the morbidity is longer and the deformities are greater from human bites.

Trauma by a human tooth occurs by actual biting or by a blow against the teeth. The trivial wound is followed by a virulent destructive lesion, due to the action of the organisms present in the mouth, with a rapid spread along the tendon

hand swells, and dusky red color appears. Soon a thin, gray, malodorous discharge begins to run from the wound. Pain on movement of the finger indicates the progression of a septic arthritis. The patient develops moderate fever and malaise, and finally appears in the hospital three to four days after the injury. At this time the whole dorsum of the hand is found to be swollen and red. Pus, similar in odor to that of a lung abscess, exudes from the laceration on pressure, either about the knuckle or on the anterior surface of the metacarpophalangeal joint. Motion of this joint is restricted and

TABLE 1.—EIGHT CASES OF HUMAN TOOTH INJURIES AT MEADOWBROOK HOSPITAL

Patient	Age of Wound	Site	Treatment	Result
M. Y.	6 days	Fourth metacarpal head	Débridement	50 per cent limitation of motion of fourth finger. 25 per cent loss of use of middle finger. Hand grip normal
R. R.	3 hours	Middle finger	Débridement	Complete function
J. L.	5 weeks	Middle finger	Amputation of hand	Loss of hand
N. F.	4 days	Third metacarpal	Amputation of metacarpal	Limitation of extension of fifth finger. Poor hand grip
J. W.	1½ hours	Fifth finger	Débridement	Complete function
W. K.	4 days	Fourth metacarpal head	Amputation of metacarpal	Limitation of motion of remaining fingers
P. H.	1 day	Over olecranon process	Incision and drainage	Complete function
T. J.	6 weeks	Third metacarpal	Amputation of metacarpal	Limitation of motion of remaining fingers

TABLE 2.—SIX CASES OF HUMAN TOOTH INJURIES AT NASSAU HOSPITAL

Patient	Age of Wound	Site	Treatment	Result
W. S.	4 hours	Fourth metacarpal head	Débridement	Complete function
C. G.	2 hours	Third metacarpal head	Débridement	Ankylosis of metacarpophalangeal joint with 50 per cent limitation of motion of interphalangeal joints of that finger
S. K.	9 days	Third metacarpal head	Drainage	Ankylosis of finger
J. O.	3 hours	Index finger	Débridement	Complete function
H. Mc.	5 hours	Fourth metacarpal head	Débridement	Complete function
G. W.	3 hours	Third metacarpal head	Débridement	Slight limitation of extension of finger

sheaths. Bites about the hand are more serious than those about the ear, face, or arm.

The organisms are streptococcus, staphylococcus, fusiform bacillus, and spirochete of Vincent. Their growth is anaerobic.

Welch<sup>1</sup> describes the clinical course of these bites as follows: "The impact of the tooth produces a laceration over the knuckles. It is tiny but deep, frequently penetrating the extensor tendon and usually entering the joint. The patient notes little discomfort for from six to twelve hours. Then the dorsum of the finger and

painful. Lymphangitis is not usual. With surgery the purulent discharge gradually diminishes and finally the incision closes in two to three weeks. Commonly about a week after the initial drainage, the amount of pus increases and the temperature begins to rise. An x-ray shows arthritis with osteomyelitis of the proximal phalanx and of the head of the metacarpal. Further drainage of the joint may result in improvement, but usually amputation of the finger and head of the metacarpal is required."

Treatment is thorough cleansing with the fingers flexed, radical débridement under tourniquet, and immobilization. Flooding the wound with zinc peroxide in distilled water is indicated.

Welch, reporting from the Massachusetts

Read at a joint meeting of the Nassau Surgical Society and the Nassau County Medical Society, March 31, 1942, Garden City, Long Island.

<sup>1</sup>Welch, C. E.: New England J. Med. 215: 901 (Nov. 12) 1936.

General Hospital, states that one in ten patients will require amputation if treated in twelve hours, while one in three will require amputation if treated from one to seven days later. An additional one-third of the patients, when treated late, have stiff fingers.

Seven cases were treated under eight hours after occurrence and seven cases were treated after twenty-four hours. Of the seven cases that were treated early, five had good function, one had ankylosis, and one had limited movement. Of the seven cases that were treated late, five lost a member or portion of a member, one had limited motion, and one had good motion of the elbow.

In summarizing the treatment of human bites it can best be stated that they are all serious lesions and require early radical débridement plus immobilization. The use of iodine in the wound, hot soaks, or minor cauterization plays no part in their treatment. All reported cases show the destructive surgery needed to cure the patient when treatment begins late. The time limit for adequate surgery is within the first few hours after the accident only.

It behooves the physician who sees these patients early to carry out the proper therapy so that the amputations are fewer and the morbidity is decreased.

Since the opening of Meadowbrook Hospital there have been eight patients admitted for human bites. Seven patients were male and one female. Three were Negroes and five white. (See Table 1.)

At Nassau Hospital we had six patients. All were males and were white. (See Table 2.)

NEW DENTAL BUR TO BE PRODUCED

A new type of dental bur with a chrome finish, which will wear at least 50 per cent longer than the steel type now in use, will soon be put into production, members of the Dental Instrument and Bur Industry Advisory Committee reported at a recent meeting, according to the War Production Board.

Laboratory studies on the chrome process have been completed, and actual production of the new specialized rs said within

Because of its long wearing qualities, industry

members said that the chrome bur will materially reduce 1944 requirements for dental burs, which are now 40 per cent above current rate of shipment.

Output of dental burs has nearly tripled in the last three years, committee members said, and the industry is continuing to expand its facilities. However, military requirements have grown even more rapidly because of the possibility of loss or damage involved in shipments made to combat areas and use under war conditions. Principal obstacles hampering output of burs are manpower shortages, rather than a lack of facilities, they pointed out.

## CONFERENCES ON THERAPY

THESE are stenographic reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with collaboration of other departments and institutions. The questions and discussions involve participation by members of the staff of the college and hospital, students, and visitors. The next report will appear in the October 1 issue and will concern "Treatment of Drug Addiction."

### Use of Sedatives and Narcotics

DR. McKEEN CATTELL: There are many special considerations in connection with the use of drugs for the purpose of producing sedation and sleep.

Manifestly, we cannot cover the whole field of the sedative drugs at this session. Rather, we plan to take up the subject from the standpoint of special problems which are met with in their therapeutic use. These problems differ in different fields of medicine, and today we will take up the subject from the standpoint of the internist, the psychiatrist, and the pediatrician.

I will ask Dr. Gold to open the discussion.

DR. HARRY GOLD: The hypnotic and narcotic agents which we might perhaps pay most attention to this morning will be the ones with which we are all most familiar—the barbiturates, chloral hydrate, bromides, paraldehyde, morphine, pantopon, dilaudid, and possibly the new synthetic, demerol.

I should like to refer very briefly to a few matters about the hypnotics which were discussed in one of the previous conferences. The terms "hypnotic" and "sedative" represent phases of the action of one and the same drug and not different drugs. The same action which causes sleep causes the sort of change we call sedation under other circumstances. Sometimes the doses are different. Although the basic action is the same, from the practical standpoint some drugs are not particularly suitable for use as sedatives during the day. For example, the rapidly acting barbiturates are not very useful for that purpose. They produce sharp peaks of effect, and the patient who needs to have his nerves quieted throughout the larger part of the day will find such a pattern disturbing. Pentobarbital, for example, is not particularly appropriate as a sedative during the day, whereas phenobarbital and barbital are because of their slow and lasting effect. With the exception of dosage all other statements of differences between hypnotic and sedative drugs break down from the practical standpoint when examined critically.

There is the question of qualitative difference

between the action of such hypnotic agents as barbital, chloral, and paraldehyde. Is the pattern of their effects upon the brain different? There is some experimental evidence on this point. If a hen is given a fairly large dose of chloral hydrate she may fall off the perch but she may not fall asleep. With a large dose of barbital, she falls asleep and stays on the perch. Here are two depressant drugs, one having a predominant sleep-producing action in which the postural reflexes are preserved, and with the other the postural reflexes may be lost with a dose insufficient to cause sleep.

There are certain peripheral actions of the barbiturates which distinguish one from another. For example, large doses of barbital and phanodorm tend to block the peripheral vagal endings, whereas large doses of phenobarbital fail to block them. Concerning what this may have to do with the patterns of effects in humans we have practically no information.

There are factors regarding the hypnotic agents which sometimes give the appearance of differences in their action; one of those factors is the speed of absorption. An hypnotic which is quickly absorbed is likely to produce an effect which is not obtained from one slowly absorbed. The sharp peak of effect is often not obtained with the barbiturate which is more slowly absorbed. The peak creates the sensation of glow and warmth. We are all, perhaps, familiar with it in relation to alcohol. I am inclined to think that patients who perceive a qualitative difference between phenobarbital and pentobarbital sodium do so because of the differences in dosage and the speed of absorption. In this connection we may note that the soluble form of the barbiturate is much more readily absorbed than the insoluble acid.

Individual variation in tolerance is very marked among all the hypnotics. A quarter of a grain, or 15 mg., will put one person to sleep and 2 grains, or 120 mg., may leave another almost without appreciable depression. That is a matter of some importance. It relates particularly to the routine

administration of a fixed dose of these compounds in making the night ward rounds

There is a tendency to give everybody the same dose. Perhaps it is all right to start with the same dose, but if we do it every night, we are not learning from our experiences. I wonder how often we analyze our experiences in our routine "hypnotic" rounds.

Here is one experience. Twelve patients between the ages of 40 and 80, suffering with insomnia, were given 100 mg. of phenobarbital sodium together with 5 mg. of morphine sulfate by hypodermic injection. A careful record kept during the night and also the following day yielded the following information: 5 of the 12 slept satisfactorily, 2 developed extreme excitement with delirium and were difficult to manage, 5 vomited, 1 had a scarlatiniform rash in the morning, and 2 itched so badly all night that they thought they did not sleep on account of the itching.

That is a bad record for a routine form of treatment of sleep difficulties of a minor variety. It might not be so bad for some of the major sleep problems encountered by the psychiatrists.

The slower acting barbiturates show cumulation. Phenobarbital and barbital are cumulative drugs.

After a patient has been taking 30 or 60 mg. of phenobarbital once or twice a day for some time there are apt to occur, although not in all people, symptoms of cumulation. There are apt to arise confusional states which we will fail to recognize for what they are if we do not bear in mind the problem of drug cumulation. This problem is less important in the case of pentobarbital or secobarbital, which is a more rapidly excreted agent, but there is cumulation in the case of these also.

Another point is the matter of dependence. Are these habit-forming? Dependence occurs with all depressant drugs. I don't know any in common use in which as the result of prolonged use there fails to arise a state of irritability and emotional unrest which differs both in its intensity and sometimes also in its quality from the state for which the barbiturate or other hypnotic was first used. I think that it is—I should like to have the opinion of psychiatrists about that—a response to the phenomenon of depression by a drug rather than due to the character of the drug. An individual who is kept in a state of more or less sustained depression by some agent is liable to develop an adaptation to that state and, as a consequence, may develop abnormal symptoms when the drug is discontinued. Irritability and emotional unrest are the usual symptoms. The degree differs with different people and the quality sometimes differs with different drugs. Certainly

it is different in the morphine group from that of the barbituric acid group.

The effect of prolonged administration of hypnotics and the effect of withdrawal was pointed out in a paper, I think by Dunning, from this hospital, in which he described several cases of convulsions following the rapid withdrawal of the barbiturates after prolonged administration.

There is just one more point about the hypnotics which I should like to make, and that is in the form of a plea for greater restraint in their use. I think that in this hospital more than 10 per cent of all prescriptions in the Outpatient Department are for hypnotics. The percentage of patients receiving them is much higher.

Is Mr. Clark around? Is that about right?

MR. D. A. CLARK: Yes.

DR. GOLD: I should like to venture the guess that only a small proportion of these prescriptions are essential. There is a tendency to prescribe phenobarbital when one is hard pressed for something to do.

There is a question of permanent injury from the hypnotics. I wonder whether anyone here has ever encountered a case of permanent injury from the barbiturates. I don't remember seeing any record of such an effect in the literature. We have some cats in the laboratory which show permanent injury, irreversible damage of the central nervous system produced by a relatively new barbiturate. I don't know that it applies only to that hypnotic. It occurred in about 8 per cent of the animals which recovered from a fairly large dose. It seems to be a more or less diffuse injury of the central nervous system with disturbances in gait and reflexes. It is a bizarre picture. In one of these animals it is present now, one hundred and ten days after the dose was given. It fell asleep, remained asleep for about twenty-four hours, woke up, and never recovered from these residual symptoms.

DR. CATTELL: The discussion will be continued, from the standpoint of the pediatrician, by Dr. Levine.

DR. SAMUEL Z. LEVINE: When I was asked to discuss sedatives and narcotics, I assumed that they fell into the general group known as the central nervous system depressants. In that group, I suppose, if one wanted to be complete in his assembly of drugs, he might include the analgesics, the preanesthetics, and the anesthetics. The total number of central nervous system depressants which are used in children is relatively small.

Generally speaking, children are more sensitive to all types of central nervous system depressants than adults, particularly to morphine and its derivatives. With the exception of the latter, the dosage for these types of drugs in children is the

same as that used for other drugs, the dosage being calculated by Clark's rule based on weight, or by Young's rule based on age, or some modifications thereof. I will consider only the drugs in common usage in children.

For analgesia, the salicylates are commonly used, in the form of acetylsalicylic acid, to relieve the rheumatic type of pain. They are not used for other forms of pain, because of their masking action on fever, since we wish to know whether the fever is due to some organic condition or not. The dosages run up to 2 to 4 Gm., or 30 to 60 grains a day, given usually at four-hour intervals. The drug is usually administered either in tablet form for older children or dissolved in a small amount of water for younger children. We do not give sodium bicarbonate with it.

For other types of pain codeine is most commonly used in younger children, and, if the pain is intense, morphine for older children. Analgesics are practically never employed in infants under a year. I presume infants do have pain, but we don't want to mask the cause of the pain by giving analgesics.

The sedatives are used, as Dr. Gold mentioned, to allay pain, to induce sleep, to diminish restlessness and irritability, and for all related types of abnormal behavior.

Of the barbiturates phenobarbital is more frequently employed than any other. As such, it is given by mouth or as soluble phenobarbital parenterally. The dose ranges from 15 to 30 mg. or from  $\frac{1}{4}$  to  $\frac{1}{2}$  grain, given at intervals of four to six hours. There may be some cumulative effect, even at six-hour intervals, since, as Dr. Gold pointed out, phenobarbital is slowly absorbed and excreted—much more so than in the case of pentobarbital, but nevertheless we employ only the former barbiturate. The reason, of course, is that there is a big margin of safety in its use, except for the occasional case of idiosyncrasy. We do occasionally see youngsters who develop fever, excitability, and, more frequently, a rash when the larger dosages are used. It is interesting that the rash may appear after the use of phenobarbital for several days, then disappear, to recur even after a week of drug therapy. I don't know if Dr. Gold or Dr. Cattell will offer an explanation of this reaction, but it has been reported. It should be remembered that these children are not given phenobarbital in tablet form, but in solution by mouth, or by the teapoc. The reaction is increased by mouth if the dose is from 3

in milk. Only rarely is it necessary to give it as an oil retention enema by rectum. If chloral hydrate is ineffective, paraldehyde may be given in dosages of from 1 to 4 cc. or from 15 to 60 grains by rectum in a small amount of tap water.

The use of morphine is limited to very apprehensive children with cardiac disease who are restless and cannot sleep, to preanesthetic use in older children, and for severe pain following operations. The dosage is calculated by either Young's or Clark's rule for infants over a year.

For relief of cough by a sedative drug, codeine is used almost exclusively in infants over a year. The same rules for dosage apply as in the case of morphine. In children under that age drugs are rarely, if ever, required for cough. In infants codeine, as well as morphine, is said to be more poorly tolerated than in older persons, although there is no good evidence that this is so.

For convulsions in epilepsy, the central nervous depressant drug most commonly used as an anti-convulsant is phenobarbital, in the dosage previously outlined. If it is ineffective, dilantin sodium is given in a dosage of 0.1 Gm. a day with a meal or directly after a meal, and is increased gradually up to 0.3 Gm. three or four times a day. The main toxic manifestation most frequently encountered is hyperplasia of the gums.

In other forms of convulsions of infants and children we have specific measures which do not require the use of the sedative group of drugs. I will merely mention them. In the convulsions of tetany, calcium salts are specific. Sedatives are resorted to only as adjuvants. Hypoglycemic convulsions require glucose. In the convulsions associated with acute glomerular nephritis with hypertension, magnesium sulfate is the therapeutic agent of choice. In convulsions which are uncontrollable by phenobarbital and not epileptic in nature, resort may be had to morphine, and even to lumbar puncture. As a preanesthetic phenobarbital is the drug of choice in young children, and morphine in older children.

In summation, then, the chief drugs, exclusive of anesthetic agents, which are used as central nervous system depressants in children are, in order of decreasing frequency, phenobarbital as well as the form of barbitol, the salicylates, chloral hydrate, morphine, paraldehyde, and dilantin sodium.

Before going on with the general remarks from Dr. Cattell, the stand of the psychiatrist. It is certainly a physician to do as possible, but the other special results and excessive

use of sedative medication. I have come to feel that one's therapeutic enthusiasm must be tempered with considerable caution. The psychiatrist, in contrast with the internist, deals largely with long-term and chronic problems, rather than with acute issues requiring sedation. In psychiatry there are several general categories of patients who need sedative medication. The largest single group are those patients who complain of insomnia from one cause or another, the two main causes being psychoneurotic disturbances of some kind and depressive disorders. In addition to those we have emergency situations made up of various kinds of excitement.

Most characteristic are the manic excitement, also the schizophrenic excitement, organic excitement, etc. There are also delirious reactions to be considered, and certain organic conditions including the large group of elderly, senile patients, who also have sleep difficulties.

In considering sleep disturbances it is necessary at the outset to remember a few basic facts. As Dr. Gold has pointed out to you, there are relatively fast-acting sedatives and there are relatively slow-acting sedatives. In the study of insomnia itself it becomes necessary to know not only how much sleep a patient is getting but also in which part of the night it is characteristically disturbed.

Three types of sleep disturbances can be defined. Some patients fall asleep very slowly, after tossing about for an hour or two, in others the sleep disturbance is primarily that of complete awakening around four or five in the morning, and in still others there is an intermittent fitful kind of sleep which runs through the whole night. One's choice of sedation in the insomnia problem, therefore, must be dependent upon the kind of insomnia which the patient presents.

As you know, generally the psychoneuroses are long-continued disturbances, and we are always reluctant to have any psychoneurotic patient embark upon a sedative career. Particularly is this true in the hospital, where we have other means for achieving relaxation, such as prolonged baths or packs, physiotherapy, massage, and exercise.

It may interest you to know that in some psychiatric hospitals no sedatives are ever employed for any situation whatever. It is very striking in a hospital in which such an atmosphere prevails that a great many sleep difficulties take care of themselves. The attitude of confidence on the part of the staff that the problem will resolve itself without the use of sedation is very important.

We use primarily the barbiturate group in our medication, recognizing these facts about them: (1) that a patient develops tolerance after a long

period of time and it usually becomes necessary to increase the dose to produce the same effect, and (2) that accumulation of the drug may develop, which he may feel as grogginess, drowsiness, or difficulty in concentration.

I think most commonly we use simple barbitol. It is cheap. It is about as efficient as any of the group. It is a drug which acts relatively slowly. It is not one which will put a patient quickly to sleep, but it is one which is likely to hold his sleep after its major action has been obtained.

The quickest-acting barbiturate I use is secobarbital. Patients regularly tell me that within fifteen minutes to half an hour they are sound asleep after using that barbiturate. It may not hold them as long as barbitol or some of its other derivatives.

Then we have that large group of patients who combine insomnia with a great deal of restlessness and agitation throughout the day. For them also it becomes necessary at times to provide some sort of chemical relief, and once more barbitol in small divided doses, 0.16 Gm. three times a day, is the most effective chemical means of affording them relaxation.

Sodium amylal has probably the most dramatic effect on motor restlessness. It is quite striking to see a catatonic stupor respond to sodium amylal. The motor rigidity disappears and relaxation appears. Patients talk who for weeks have been mute. We not infrequently use that drug intravenously in 0.4 to 0.6 Gm. doses given slowly over a period of fifteen minutes to a half hour, watching the pulse, the blood pressure, and the eyes for danger signals.

For acute excitement, our drugs of choice are paraldehyde and chloral hydrate. That is particularly true in delirious reactions and especially so in alcoholic delirium tremens, in which paraldehyde is by all odds the drug of choice. We use here perhaps more heroic measures than in general practice—15 cc. of paraldehyde by mouth and as much as 20 to 25 cc. by rectum if necessary. It is infinitely preferable in emergency cases to give a large initial dose than to have to repeat the dose three hours or six hours later because the amount was inadequate to quiet the excitement in the beginning.

When one turns to the group of elderly senile patients, a word of caution is necessary. These patients do not tolerate sedatives as well as younger people. Drugs may accumulate more readily in them because of renal inadequacy. They are also more prone to toxic manifestations. Therefore, we prefer not to use strong sedatives in elderly, senile patients. Perhaps the least troublesome we have found is a drug called sedormid, which seems to work very well in these individuals.

## *To secrete, to excrete, or both?*

When lipase, the fat splitting enzyme from the pancreas is deficient and fats are imperfectly digested, the effect may be a lack of energy, too rapid heat loss, and failure to fill out the body contours—all a result of dysfunction of a secretion.

Desoxycholic acid has been shown to produce a marked increase in the activity of lipase.

Bile too is a secretion but it is known now as more—it is an important excretion as well. Bacteria, albumin, acetone, uric acid, urea are substances that

in disease may make their exit in bile.

Dehydrocholic acid is the greatest encourager of the flow of dilute bile. In its lavage of the bile ducts it helps carry out mucus, dried bile, and with them, when present, other undesirables.

This dual purpose, secretion—excretion, is stepped up by one agent—

## DOXYCHOL

Doxychol is desoxycholic acid  $1\frac{1}{2}$  gr. and dehydrocholic acid 3 gr. The tablets are in bottles of 100, 500, and 1000.

"The physician should make certain of the potency of the particular preparation which he employs and consider this factor in arriving at the proper dosage. Particular care regarding dosage should be exercised if any change is made in the brand of thyroid employed."\*

## Thyroid *Duo-Sayed* Answers This Problem

You are well aware of the numerous statements that have appeared in medical literature emphasizing the need for greater uniformity in thyroid medication.

McNeil Laboratories assure the highest uniformity by using the double assay method in preparing thyroid for medication. Each lot of Thyroid *Duo-Sayed* is standardized for both total iodine content and thyroxin content.

## Thyroid *Duo-Sayed* (McNeil)

is a guarantee of the highest degree of purity and uniformity in thyroid preparations.

# SOPRONOL Inhibits FUNGOUS INFECTIONS

**MONILIA**  
*albicans*

**EPIDERMOPHYTON**  
*inguinale*

**MICROSPORUM**  
*audouinii*

**TRICHOPHYTON**  
*purpureum*

... As demonstrated by clinical investigation  
in a leading United States hospital

In tests on a large number of hospital patients, Sopronol was found to exert an *inhibitory* rather than a destructive action on the fungus. The advantages of this method are obvious. Sopronol, taken readily into the fungous organism, prevents its development and spread. Hence the infection is quickly brought to an end, but without the customary skin irritation caused by poisonous by-products resulting from strong fungicides in contact with the mold. The chemical basis of Sopronol is sodium propionate.

## ALL SUPERFICIAL MYCOSES (RINGWORM)

Prescribe Sopronol for: Tinea Pedis, Tinea Cruris, Tinea Capitis, Tinea Glabrosa, due to "the dermatophytes"—Trichophyton, Epidermophyton, Microsporum, Monilia (Candida) and pathogenic aspergillae infections. Sopronol is non-irritating, non-keratolytic, non-toxic.

*Available in alcoholic solution, powder  
and water soluble ointment bases*

# UNINTERRUPTED TREATMENT...

## UNINTERRUPTED SLEEP

SUCH local inflammations as chest colds, sore throats, sprains, strains, contusions, boils, carbuncles can interfere seriously with the patient's required sleep and relaxation.

By providing analgesia and decongestion for eight hours or more from a single application,

**NUMOTIZINE**  
**THE PRESCRIPTION CATAPLASM**  
**NUMOTIZINE**

permits the patient to sleep without interruption throughout the night.

With Numotizine there is no necessity for frequent changes of dressings, no hot water bottles, no oral analgesic medication to upset the stomach.

Numotizine contains guaiacol, beechwood creosote, methyl salicylate, sol. formaldehyde, in a base of C. P. glycerine and aluminum silicate.

Easy to apply—easy to remove. Supplied in 4, 8, 15 and 30-ounce jars. Ethically promoted—not advertised to the public.

**NUMOTIZINE, INC., 900 NORTH FRANKLIN STREET, CHICAGO, ILL.**

# Gratifying Relief in "Sore Throat"

with

## Aspergum

When the patient chews Aspergum a soothing flow of saliva laden with acetylsalicylic acid is released. Thus effective analgesia is brought into *immediate and prolonged* contact with all pharyngeal areas, including those often not reached by gargling or irrigations.

Moreover, chewing provides a gentle stimulation of surrounding muscles, helping to relieve local spasticity and stiffness, promoting tissue repair. The patient is more comfortable, willingly assumes a suitable diet earlier; convalescence is hastened.

### Indications for the use of Aspergum:

1. Post-tonsillectomy care
2. Acute and chronic tonsillitis, pharyngitis, "sore throat" of influenza, "Grippe", etc.
3. Acute coryza (with accompanying pharyngeal irritation)
4. Non-specific upper-respiratory infections

Aspergum is available in packages of 16, moisture-proof bottles of 36 and 250 tablets.

Ethically promoted—not advertised to the lay. White Laboratories, Inc., Pharmaceutical Manufacturers, Newark 7, N. J.

### Postwar Medical Service

With the approval of the Surgeons General of the Army, Navy, and Public Health Service, a questionnaire has been sent by the A M A to 3,000 of the 50,000 medical officers in the armed services, as a pilot experiment. It is sought to define the size, scope, and type of postgraduate instruction at the various levels of intern, resident, and specialist training for the postwar period.

Nine hundred and twenty-seven replies had been received by June 1 of this year.

"Questionnaires were divided into four groups for study on the basis of licensure or medical school graduation. In general, licensure was used, since there was a section that dealt with licensure. However, recent medical graduates who entered the armed forces without a license to practice medicine were classified in the year they would normally have become licensed. Group 1 consisted of those licensed from 1937 to 1943. Group 2 consisted of those licensed during the years 1930 to 1936. Group 3 consisted of those licensed during the years 1920 to 1929, and Group 4, the oldest group, consisted of those licensed before 1920. There were the following number of returns in each group

	Number	Percentage
Group 1	400	43
Group 2	323	35
Group 3	168	18
Group 4	36	4
Total	927	100%

Greatest interest in postwar medical education was evident among the youngest officers—those, for example, who graduated or would have graduated between the years 1937–1943. Three hundred sixty-four, or more than 90 per cent, want some additional training. Among the men 35–42 years of age 74 per cent wanted further education. Of those who graduated between 1920 and 1929 three-fourths wanted additional training. And of those, the smallest group, who graduated before 1920, one-third were already specialists, and few desired more training.

In the matter of industrial medicine, only 56 per cent of the graduates between 1937 and 1943 were interested. Of the group who graduated in 1930–1936, 108 men out of 323, or about one-third, were attracted

to this type of practice. The older group, those who graduated from 1920-1929, were interested only to the extent of 27 per cent; of these 17 wanted full-time work and 28 part-time appointments. The oldest group, those who graduated before 1920, were very little interested, only 6 out of 36 desiring industrial practice.

Licensure and practice interested a large proportion of the medical officers. In the youngest group, graduates of 1937-1943, 41 per cent planned to re-engage in private practice in their previous locality. In Group 2, 73 per cent wanted to return to their former places of practice. In Groups 3 and 4—1920 and earlier graduates—80 per cent wanted private practice again in their prewar localities.

Regarding economic considerations a wide variety of answers came in, some desiring general practice, some group practice, but of the youngest group only 5 per cent wanted to remain in government service. In the group of graduates of 1930-1936, 10 per cent would stay in government service and in the group who graduated in 1920-1929, 17 per cent would remain in government employ. The oldest group was most interested in remaining in government service. About 30 per cent of this group would do so.

The full report of Lt. Col. Harold C. Lueth, of which the foregoing is an incomplete synopsis, merits careful reading and study by all who are concerned with the interests and needs of returning medical officers. The report of the A.M.A. Com-

mittee on Postwar Medical Service had this to say:

"The committee's discussions ranged widely over the field of postwar medical service. Already, with the approval of the Surgeons General of the Army, Navy, and Public Health Service, a pilot questionnaire was sent to 3,000 medical officers in these three services. This was carried out by a subcommittee consisting of Drs. Abell, Mason, and West, who had the invaluable assistance of Lieutenant Colonel Lueth, Surgeon General's Liaison Officer, who has an office in the headquarters of the American Medical Association. At the meeting on April 29, Lieutenant Colonel Lueth was able to present some very illuminating data. Authorization has now been obtained to send a somewhat revised questionnaire to all the medical officers in the Army, Navy, and Public Health Service. I think it is safe to say that this questionnaire will receive a very favorable response. It will make the medical officers feel that they are not forgotten men. Obviously, the data derived from these questionnaires will be of fundamental importance in determining what direction the committee's activities should take in meeting the needs of the returning medical officers.

"The data from these questionnaires should indicate the size, scope, and type of postgraduate instruction at the various levels of intern, resident, and specialist training, and of other forms of postgraduate instruction required. The Council on Medical Education and Hospitals of the American Medical Association is already at work in this field."

This study and those which will undoubtedly follow it are highly commendable and should point the way to provision of necessary facilities to accommodate the needs of returning medical officers after the war. All are urged to give this report the attention and study it deserves.

## First Things First

Medicine has progressed, developed, flourished under nearly every kind of government which has had the common sense to let it alone. It has developed great leaders, good hospitals, and has conquered many of the world's greatest disease scourges.

As a nation we are living longer, living healthier lives than almost any comparable group of people. This objective has been reached by medicine in spite of the fact that housing, sanitation, distribution of national resources, working conditions, and wages, all accessories to the promotion of the national health and welfare to which the

government of this country is constitutionally pledged, have lagged far behind.

What might be expected, for example, if the government instead of arousing the public to expect medical care through social security legislation, were to furnish American medicine with the help it needs by securing to the people proper housing, good nutrition, proper sanitation, abolition of slum areas, unfavorable working conditions, and adequate earnings *after* taxation?

It is our opinion that most people consider medicine a human institution, recognize the fact that as a human system it has faults

but that it has kept the people of this country well, made them longer lived, and provided them with a good doctor for nearly every occasion when a doctor was needed. It has *not* given them politics or argument when they needed medicine. It has not promised them social security or any other panacea when they needed surgery. It *has* undertaken to educate and train good physicians and surgeons. That it has succeeded is evidenced by the medical care the troops are receiving, by the kind of medical care the civilian population is receiving in spite of the withdrawal for service with the armed forces of thousands of the best trained men and women available.

And all this has not increased the general morbidity rate. The quality of the public health still remains high. People still continue to live longer—except the doctors.

We believe that the greatest benefit to the people and the greatest help to the physicians would be derived by the attention of

government to the first things within its proper province which could *assist* American medicine to better its record of achievement in the promotion of the public health. Unification of its sprawling departmental dabbling in medical affairs has been urged for many years—to no purpose, apparently.

A little cleaning of the government house, a little putting in order of existing government affairs as they relate to medicine, seems to us to be indicated. Medicine, as we said, has flourished when governments have had the sense to let it alone. What could it not do with a little real help in the proper places, a little real representation in the Cabinet, for instance?

One reason for the very real successes of military medicine is the frequency with which commanding officers ask the advice of and are guided by their medical officers. Experience has proved the practical, life-saving value of this procedure. Maybe there is a moral here somewhere.

### Serum Albumin, a Blood Substitute

Research for blood substitutes continues without surcease. There is no need to detail the value of blood and plasma for medical and surgical emergencies, yet it is readily apparent that these precious fluids are not unlimited, and are not always available at the very moment when time is of the essence. Dried human plasma is one effective answer to this problem, but simpler is the substitution of a more elementary substance which can readily restore a falling blood volume to normal. The fractionation and purification of the various serum proteins by E. J. Cohn and his coworkers have been a distinct contribution and advance in the field of blood substitution.<sup>1,2</sup> The chemical and biologic properties of serum albumin of related species have also been investigated from the same viewpoint.<sup>3</sup>

The chemical properties of human and bovine serum albumin are almost the same. The size, shape, and electric charge of both molecules differ so slightly that a mixture of both proteins is quite homogeneous. However, they differ in chemical constitution, crystallization, and in immunologic properties. The osmotic pressure of both albumins is almost the same, a physical property useful in the treatment of shock. Serum albumin is the most stable and soluble of the

serum proteins, and a 25 per cent solution has a low viscosity.

Experiments in dehydration and blood loss by venesection to the point of a 20 per cent reduction of blood volume demonstrated successful restoration by the administration of a 25 per cent solution of serum albumin in adequate amounts. This solution is well tolerated when injected at the rate of 5 cc. per minute. When the albumin is not precipitated with scrupulous technic, epigastric pain and precordial distress have been known to result from its administration. Wheals occasionally result from the infusion of serum albumin. Fluid is drawn into the circulation with mathematical precision. Each gram of albumin attracts 17.4 cc. of fluid into the circulation (13.2 to 24 cc.). A unit dose of 25 Gm. of albumin may confidently be expected to increase the circulating plasma by about 450 cc. Serum and urinary potassium are virtually unaffected by such injections. Significantly, there was no essential difference between bovine and human albumin in their ability to draw fluid back into the circulation.

Human serum albumin has already been tried and tested in the sphere of military medicine.<sup>4,5</sup> Its use should be extended, for it is an effective agent in restoring the blood volume, and has

been used in the treatment of nephrosis. For such purposes it is as satisfactory as blood or plasma.

Its concentrated form and its easy storage properties constitute definite advantages. If further studies prove that its chemical cousin, bovine serum albumin, with its kindred physico-chemical and physiologic properties, is safe for human use, the field of blood substitution bids fair to be tremendously extended by the ad-

dition of a new, readily available, and relatively unlimited source of serum albumin.

## The Postcholecystectomy Syndrome

The removal of a gallbladder, diseased or otherwise, frequently fails to relieve the patient of his symptoms. The feared, familiar colic with its typical radiation may still haunt the sufferer. These attacks of pain may be accompanied by nausea, vomiting, transient jaundice, and occasionally fever. Abdominal tenderness and mild icterus may be among the residual physical signs. This postoperative symptom complex is so definite that it has been entitled the postcholecystectomy syndrome.

Statistics show that 30 to 40 per cent of those, who have undergone cholecystectomy continue to suffer from this syndrome, the causation of which, until recently, has been somewhat of an enigma. A pertinent operative finding in this group is the frequent failure to discover calculi in the absence of pathology in the gallbladder, in spite of preceding attacks of typical colic. It is refreshing to learn that the modern surgeon is sufficiently versed in physiology to direct and develop his surgical technic along the lines of functional pathology and devise operative procedures designed to correct the altered physiology.<sup>1</sup>

The cause of the postcholecystectomy and perhaps the precholecystectomy symptoms may be due to a dyskinesia of the biliary sphincter mechanism. The distribution of a sphincter system along the biliary tract and the importance of its malfunction has been thoroughly emphasized in recent literature.<sup>2,3,4</sup> The nature of the symptoms is dependent on which sphincter mechanism is disturbed. The spasm itself may be initiated by local or intrabiliary causes such as residual calculus, infection, or traumatic stricture. In other cases the dyssynergia apparently

has a functional, not an organic basis, akin to spastic colitis. The hepatic, biliary, or pancreatic sphincter, or the sometimes present ampullary sphincter may cause varying syndromes. Spasm of the hepatic sphincter causes hepatic pain and jaundice. It is evident that spasm of any sphincter may increase the intraductal pressure to the point of producing colic. Removal of the gallbladder will yield little relief if the source of the pain and other symptoms, the abnormal sphincter, is left undisturbed. Some gain ultimate relief by the physiologic adaptation of the sphincters and bile ducts subsequent to the cholecystectomy, for spasticity is not necessarily a permanent condition.

Facts have been presented to show that dyskinesia of the sphincter mechanism plays a leading role in the production of certain types of biliary disease. These symptoms may persist after cholecystectomy. If medical treatment is of no avail and investigation leads to the conclusion that dyssynergia is the basis for this symptomatology, surgery should be considered. If no pathology is revealed after careful exploration, operative procedures may be indicated to relieve the sphincter spasm. Surgical technic may take several forms<sup>1</sup> and should be familiar to internists as well as to surgeons for the proper comprehension and amelioration of a trying and subtle syndrome.

# REGIONAL ANESTHESIA IN THE ARMY

STEVENS J. MARTIN, MAJ., (MC), AUS

FROM time immemorial, pain has been the scourge of humanity. Its relief will be forever the hope of millions and the perennial task of medicine. To the anesthetist, pain presents a daily challenge among the civilians and the military alike. Modern medical advances now afford the pain-stricken a choice in their relief: either a local or a generalized depression of their sensorial apparatus. For many reasons, it is often an advantage, if not a necessity, to select the former, better known as regional anesthesia.

Regional anesthesia is of comparatively recent development, although it received its initial impetus some time ago through the invention of the hypodermic syringe by Charles G. Pravaz in 1851 and its application in the alleviation of pain with morphine by Alexander Wood in 1855,<sup>1</sup> the introduction of cocaine as an anesthetic solution by Koller<sup>2</sup> and Halsted and Hall<sup>3</sup> in 1884, with its intrathecal injection by Corning a year later, and the discovery of procaine by Einhorn in 1904.<sup>4</sup> The most significant strides have been made in the present century with the refinement of old techniques and the introduction of new ones, the preparation of new and perhaps better anesthetic solutions, and, above all, with a more wholesome appreciation of the anatomic limitations and clinical evaluation of the many procedures employed. These advances have been reviewed recently in publications by Tovell,<sup>5</sup> Rovenstine,<sup>6</sup> Odum,<sup>6</sup> Nicholson,<sup>7,8</sup> and Lundy *et al.*<sup>9</sup>

Regional anesthesia, in the broad sense of the word, includes topical application, local infiltration, localized freezing (cryoanesthesia), field block, nerve block, subdural and epidural procedures, and sympathetic ganglion blocks. Its essential features, in contrast to general anesthesia, may be regarded as (1) preservation of consciousness, or, at least, no further depression than before anesthesia; (2) marked decrease or loss of central nervous system irritability, chiefly in the operative field; and (3) minimal interference in the respiratory and cardiovascular systems of the body and their compensatory mechanisms. This, in turn, results in (4) liminal changes in metabolic economy—i.e., gaseous exchange, heat, fluid, and electrolyte balance.

These features may represent advantages which in some (spinal) anesthetics may not be easy to obtain.

To the military anesthesiologist, there may be other notable advantages of regional anesthesia.

These may be briefly enumerated as (1) simplicity and portability of equipment; (2) availability, stability, compactness, and nonexplosiveness of agents employed; (3) wide margin of safety in properly selected cases; (4) freedom of action in attending to mass casualties and preparing them for surgical teams; (5) few or no postanesthetic complications; (6) conservation of personnel in the postoperative care of patients; and (7) ease and relative safety of evacuating patients anesthetized by regional anesthesia.

The competent anesthetist, however, must be mindful also of significant disadvantages of regional anesthesia. These may include the limitation of time of anesthesia imposed on the surgeon, often inadequate relaxation and exposure of the operative field, technical exactitude, and time necessary to perform the various procedures, the necessity of knowing thoroughly the limitations and contraindications of the block, the suitability of the patient for regional anesthesia, possible idiosyncrasy or pharmacologic toxicity to the drugs employed, the presence of multiple wounds, and the presence of infection or trauma near anatomic landmarks of the procedure.

Regional anesthesia, *per se*, has only recently been employed in the alleviation of pain and preparation for surgery of combat casualties of the American Army.<sup>10</sup> It was unheard of in the Civil War and was only occasionally employed in the Spanish-American conflict. In the form of local infiltration anesthesia, it was first fully appreciated in World War I.<sup>11,12,13</sup> Spinal anesthesia also became popular in that conflict,<sup>11,14</sup> being employed for various types of emergency surgery<sup>15</sup> and gassed patients.<sup>16</sup> Other types of regional anesthesia, however, particularly field and nerve blocks and sympathetic ganglion block, have received little or no attention in previous wars. Their advantages have been appreciated by the military surgeon, patient, and anesthetist only since the onset of the present global war. Publications<sup>17,18,19</sup> and personal communications<sup>20</sup> from army anesthetists in the European, African, Far East, and Central and South Pacific theaters of war, as well as from the Zone of Interior, have been plentiful and have served already to emphasize the growing popularity of regional anesthesia. From such reports it may be stated safely that its addition to the anesthetist's arma-

mentarium has made him more indispensable to his surgical unit.

### Overseas Surgical Installations

Regional anesthesia, of one type or another, is practiced in numbered as well as named hospital units. This fact is not at all surprising when it is realized that trained anesthetists are assigned to such organizations<sup>21</sup> and that certain fundamental equipment, such as procaine, syringes, and needles, are issued to all medical echelons. A series of sixty-seven letters from friends and former student anesthetists trained at Tilton General Hospital<sup>20</sup> has emphasized the desirability and necessity of administering regional anesthesia to their combat casualties. The remarkable and interesting fact is that no comment was forwarded about lack of specialized regional anesthesia equipment, for they have all learned to do their procedures quite satisfactorily with standard items. This should be an instructive lesson for us all.

Many factors determine the type of anesthesia—regional or general—that can be employed in overseas installation. These have been emphasized in previous reports.<sup>21,22</sup> Aside from the anesthetist's own technical ability, perhaps the most significant factors are climate, type and location of surgical unit, and combat conditions. Thus, in England, where regional anesthesia is not popular, it is not commonly employed. In units located in Africa, Sicily, and India, regional anesthesia was not only ideal in some units but also a matter of necessity. Pain relief and preparation for surgery of mass casualties near combat areas in tropical heat with poor vaporization of anesthetic solutions, with the need for early evacuation of patients, presented formidable problems to the anesthetist. While spinal anesthesia was once popular in these areas, local infiltration, as recommended by the Russians, and nerve blocks are the more favored regional techniques now.<sup>20</sup> In the Australian theater of war enthusiasm for regional anesthesia is endemic and depends apparently more upon the anesthetist than on any other factor. Reports from units in the same general locality are conflicting. A few dislike regional anesthesia, saying it is not satisfactory, while others feel it is almost ideal. In all theaters of war, the regional anesthesia techniques are those commonly employed in civilian institutions, the most popular being local infiltration and brachial plexus, paravertebral, and caudal block techniques. Due to censorship, the number of regional anesthetics performed cannot be disclosed. However, it may be stated that preference as well as necessity favors operative rather than diagnostic or therapeutic block procedures.

### Regional Anesthesia at Tilton General Hospital

Regional anesthesia was administered to 2,625 patients at Tilton General Hospital with gratifying results. This number is admittedly small and constitutes but a part of the total group of patients receiving anesthesia. However, many facts have been learned from the regional anesthetics performed, some of which may be of interest and value to civilian and military anesthetists alike.

With the exception of some of the topical and local infiltration anesthetics, the regional techniques were performed by student officer anesthetists and/or the Section Chief. Premedication was greater, as a rule, in comparison to civilian patients, and was administered to all patients. Those on whom regional anesthesia was performed for surgery received 0.015 Gm. of morphine sulfate and 0.0006 Gm. of scopolamine about one hour and 0.1–0.3 Gm. of nembutal thirty minutes before the block. Patients on whom a diagnostic or therapeutic block procedure was carried out were given only the barbiturate. All procedures were performed with the usual surgical aseptic precautions. The following agents were employed, depending upon the choice of the anesthetist and type and purpose of regional anesthesia: 4 per cent cocaine hydrochloride or 1–4 per cent pontocaine hydrochloride for topical anesthesia, 1 per cent procaine hydrochloride for local infiltration and field block with neosynephrine, 2 per cent procaine hydrochloride for nerve, epidural, and sympathetic ganglion blocks, 5 per cent procaine hydrochloride for continuous spinal anesthesia, and 10 per cent procaine hydrochloride, 10 per cent metycaine, 1 per cent pontocaine hydrochloride, and nupercaine in 1:1,500 solution for the classic subdural spinal anesthetics. Dosages were determined by the same criteria as employed for civilian patients. An interval of five to thirty minutes, depending upon the type of regional anesthesia, was allowed before the success of the procedure was evaluated.

Specially constructed syringes and needles are always desirable for the techniques of regional anesthesia. While such items are, at present, non-standard, one set was available for our staff. However, experience and the necessities of military expediency have proved that successful regional anesthesia can be performed with standard equipment issued to all surgical installations. This has been not only our finding but also that in many other hospitals here and abroad.

The total number of regional anesthetics performed has been summarized conveniently in Table 1. It can readily be seen that a wide

variety of techniques have been employed, all of which are established and well-known procedures and commonly employed in university and other civilian hospitals throughout the country. About 94 per cent consisted of operative anesthesia and the remainder of diagnostic and therapeutic techniques. The incidence of success varied not only with the type of regional anesthesia performed and its specific technique, but also with errors in properly selecting patients mentally adapted for such procedures, misjudgment as to the duration of surgery, and the technical ability of the anesthetist. Successful techniques were obtained in approximately 85 per cent of the operative cases (45-100 per cent) and about 60 per cent (35-80 per cent) of the diagnostic and therapeutic procedures. Inhalation or intravenous anesthesia was administered in instances in which operative blocks failed or wore off.

Complications of major and minor character have occurred, none of which were fatal or refractive to treatment. No sequelae, infections, or gangrene were noted after any regional anesthesia. The major complications consisted of the following: two moderate and two severe toxic reactions to 4 per cent pontocaine applied topically in preparation for bronchoscopy, one severe toxic reaction to 1.5 per cent meprocaine given for our first continuous caudal anesthesia, one foot-drop following a sciatic nerve block for sciatica which was successfully treated by physiotherapy, 11 cases of various degrees of atelectasis, and 2 cases of bronchopneumonia after a single injection and continuous spinal anesthesia for nephrectomies and upper abdominal surgery. In all instances, the complications were not due to the agent per se or to the choice of procedure, but chiefly to poor technique or to inadequate post-operative care, as in the case of atelectasis.

Minor complications were no more frequent than those noted in civilian patients and consisted chiefly of variable degrees of vascular and respiratory depression, nausea and emesis during high level spinal anesthesia, headache, mild to moderate, urinary retention, and, infrequently, a backache after spinal anesthesia, and transient vertigo, nausea, and emesis in three instances after paravertebral block procedures.

### Diagnostic and Therapeutic Block Procedures

Of particular interest have been the type and number of diagnostic and therapeutic procedures performed at Tilton General Hospital. They have also been instructive and often a challenge. Above all, they have served significantly in developing keen cooperation among our internists, surgeons, and anesthetists in our common and academic approach to the problems of our patients. Thirty-two diagnostic procedures were performed. These procedures, with the indications, are listed in Table 2.

Many of these techniques were subsequently repeated as therapeutic procedures, while surgery followed in a few instances (see Table 2). The most interesting findings were noted in the first group of patients, most of whom were neurosurgical casualties, the rest being orthopaedic patients. The incidence of success with stellate and thoracic or lumbar sympathetic blocks in this group was high (80 per cent) and very gratifying to both patient and surgeon. Relaxation of the blood vessels with the resulting improved circulation practically always eliminated pain of vasospastic origin, if the pain persisted after the blocks were successfully accomplished, it was concluded that the pain was of somatic origin. The

number of diagnostic procedures performed in Groups 2 through 5 is too small to justify any comment. However, it may be stated that the technics employed in Groups 2 and 5 were all diagnostically successful. The most discouraging results were obtained in attempting to determine somatic versus visceral pain (Group 3) and the intervertebral disk versus the peripheral nerve origin of sciatic pain (Group 4).

Therapeutic block procedures were performed in cases not requiring a diagnostic approach and in all instances where the diagnostic technics were initially successful and where surgery was contraindicated or not contemplated. A series of 129 procedures were done which consisted essentially of lumbar sympathetic ganglion blocks, stellate ganglion blocks, paravertebral (spinal nerve) blocks, and others, as noted in Table 3. With the exception of 14 patients, it was found necessary to repeat the blocks two to eight times to obtain alleviation of symptoms for several months. While the initial paravertebral spinal nerve block, stellate ganglion, or thoracolumbar sympathetic ganglion block was effective for from several hours to two days, each subsequent procedure prolonged the effect in a geometric ratio extending into days, weeks, or months. Absolute or 95 per cent alcohol following the procaine injection was never used. The onset of relief was rapid (five to twenty minutes) in most instances, and often dramatic. The indications and type of therapeutic block employed are listed in Table 3.

The number and variety of indications for therapeutic regional anesthesia have been numerous. As with the diagnostic procedures, a high average incidence of success of 60 per cent (35-80 per cent) was obtained. Somatic pain was more difficult to treat, especially when referred from the viscera or when it originated in metastatic carcinoma. No ammonium preparations were available for the latter. Of particular value were the procedures performed for pain, cyanosis, edema, and coldness of the extremities due to vasospastic disturbances. Occasionally the results were dramatic and spared the patient a sympathectomy. These effects were determined subjectively by the patient and also objectively by noting changes in color, skin temperature, and increases in circulation time of the extremities (determined by the Section on Cardiovascular Renal Diseases). In seven instances there was a significant, measured decrease in the circumference of the calf and ankle regions in cases of chronic edema due to prolonged vasospasm.

## Discussion

Regional anesthesia is now an accepted procedure in military surgical installations as well as in

TABLE 2.—INDICATIONS FOR DIAGNOSTIC PROCEDURES EMPLOYED

Group	Indications	Technic Employed	Number
1	Determination of: Somatic vs. sympathetic (vasospastic) pain	Stellate or lumbar sympathetic block	16
2	Value of proposed sympathectomy for extremities	Stellate or lumbar sympathetic block	5
3	Parietal vs. visceral pain	Differential paravertebral block, zonal epidural anesthesia, or local infiltration	5
4	Intervertebral disk vs. peripheral nerve origin of sciatic pain	Paravertebral block or sciatic nerve block	4

Total			32

civilian hospitals. Its practice in medical organizations overseas emphasizes its growing popularity and suitability for military casualties at field units. All types of regional anesthesia in numbered installations and at Tilton General Hospital, with the exception of cryoanesthesia, have been employed. The specific technics used have been the established procedures of Labat,<sup>23</sup> Rovenshteyn,<sup>24,25</sup> Tovell,<sup>4</sup> Lundy,<sup>9</sup> Lemmon,<sup>26</sup> and others. Sympathetic ganglion blocks employed were similar to those described by White,<sup>27</sup> DeBakey and Ochsner,<sup>28</sup> and Nicholson.<sup>29</sup> New methods have not been devised, except for the modification of the Taylor technic.<sup>30</sup>

The total number of regional anesthetics performed at Tilton General Hospital is too small to justify a statistical analysis or a comprehensive evaluation of the various procedures employed. However, from the data presented, certain interesting facts may be noted. The variety of procedures used, their indications, and the incidence of success compares favorably with results obtained at civilian institutions. Complications were just as varied and perhaps as severe as at civilian hospitals. It is gratifying to know that despite a continuous stream of students<sup>31</sup> assigned to the school of anesthesia at this post, who helped perform some of the regional anesthetics, no fatalities or sequelae occurred.

The number of sympathetic ganglion blocks performed was high. This is undoubtedly due to the increased incidence in this war of injuries of the extremities and their peripheral nerves as well as to the presence of a neurosurgical center at Tilton General Hospital. In performing therapeutic ganglion blocks no alcohol was employed, not only to avoid local neurolysis, which would make subsequent surgery more difficult, but also because often one or two procaine procedures would produce lasting results. No anesthetic

## Discussion

Dr. Arthur M. Suffin, M.D., *Hempstead, New York*—I was particularly interested in Major Martin's report on diagnostic and therapeutic nerve blocks for vascular diseases of the lower extremities. Ochsner and DeBakey reintroduced in 1939 and, what was more important, gained wide recognition in pointing out the value of lumbar sympathetic block for thrombophlebitis. This block is directed solely at the abolition of vasomotor influences to the lower extremity. The elimination of the reflex spasm improves arterial circulation and venous return which in turn aids lymph drainage, thus reducing the edema and improving the color and lessening the coldness. Frequently, this block is followed by a marked diminution or elimination of pain. This is merely a happy coincidence. The mechanism of this pain relief is interesting and as yet unsettled. The great weight of experimental evidence is against the conception that pain impulses from the periphery traverse the sympathetic ganglia on their way to the cord and cortical centers. Evidence indicates that all pain impulses from the extremities reach the cord by way of the posterior root system without passing through the sympathetic chain. We therefore cannot accept an explanation which supposes that the lumbar sympathetic block has resulted in a physiologic lesion of centripetal pain fibers. Moreover, we know from many clinical cases that surgical sympathectomy leaves sensation in the normal unaltered. Antidromic conduction in efferent sympathetic fibers

has been postulated. This has not been generally accepted. We are left, therefore, with the currently accepted theory of vasospasm as the origin of the pain with the posterior root system relaying it to the brain. Whether one believes in the ischemic theory or the tension theory of muscle pain is immaterial, since both mechanisms operate in thrombophlebitis. The blocking of the centrifugal vasomotor influences supposedly releases the arterial spasm, breaks up the vicious cycle, and restores normal circulation. It is quite conceivable that the deposition of a sufficient quantity of anesthetic solution paravertebrally in relation to the sympathetic ganglia and rami communicantes may easily diffuse posteriorly to anesthetize the somatic trunks carrying pain fibers from the lower extremity.

As regards diagnostic procedures for peripheral vascular disturbances, I believe that a median block at the wrist or an ulnar block at the elbow for the upper extremity, and an anterior or posterior tibial block for the lower extremity, are more efficacious for differentiating organic narrowing or occlusion of peripheral vessels from vasospastic narrowing. So frequently, after what appears to be a successful stellate ganglion or lumbar sympathetic block, there will be demonstrated a further rise in skin temperature over the anesthetized region following a more peripheral interruption of vasomotor fibers. This is more practical and gives more consistent and reliable results.

That vasospasm plays an important role in causal-gic states is exemplified as Dr. Martin has indicated by the more gratifying results following sympathetic block in those patients presenting an extremity that is cold, painful, with hyperidrosis usually, and color changes.

Finally, any radical sympathetic, posterior root, or cord surgery for painful amputation stumps should be preceded preferably with a spinal anesthesia to the appropriate level. If the pain is not relieved, surgery is useless and a good deal of time and suffering will have been saved.

## MEDICAL TRIUMPH

Dr. William H. Ross, chairman of the board of trustees of the Medical Society of the State of New York, meeting at the Hotel Pennsylvania, advanced yesterday [May 9] toward the retiring president, Dr. Thomas A. McGoldrick, to award him a gold medal.

The applause was so vigorous that a large screen behind the speakers' dais teetered and fell toward Drs. Ross and McGoldrick. Two other physicians and a rear admiral grabbed the screen and held it as a canopy over the heads of the principals as they went through the ceremony. Not a twitch showed in Dr. McGoldrick's buccinator muscle, nor was there a quiver in Dr. Ross's oculomotor nerve, a superb example of perfect control.—*New York Herald Tribune, May 10, 1944*

## WAR AGAINST DISEASE

The prevention of disease and the prevention of war are today the two great world problems. The way is pretty plain in this matter of war, be it against a pathogenic microbe or against a pathologic nation of people. As we have organized preventive medicine, we must organize preventive war. In medicine we do not talk about peace with the disease, with the parasites, with the tubercle bacillus, for example. We do not propose to write a peace treaty with these causes of disease. We do not sit around a peace table with our disease-producing enemies. We wage continuously either an active or preventive war. We should have a continuous preventive war program fashioned along the lines of our continuous preventive disease program.—*David John Davis, M.D., Diplomat, Jan., 1944*

# OBSERVATION OF ANORECTAL DISEASE AND PILONIDAL CYSTS IN AN ARMY HOSPITAL

J E ALFORD, Capt., (MC), AUS, Fort Jay, New York

THIS paper is based upon observations made in a station hospital within the continental United States which accepts and treats officer and enlisted personnel on duty within the area serviced by it, or casual personnel on furlough within this area. This hospital does not receive battle casualties from overseas, therefore, the patients treated by us are very similar to those seen in civilian hospitals except for two notable exceptions. They are all men and fall within a fairly narrow age group and are leading a more active life than they were formerly accustomed to. Army life is much better regulated as to dietary and sanitary habits, and, while they work harder, their environment is much better.

It is interesting to note that in the year 1943 the cases falling within the interest of a proctologist that were admitted on the surgical service constituted 11 per cent of all the admissions. These included hemorrhoids, 51 per cent, pilonidal cysts, 27 per cent, perirectal abscess, 7 per cent, fistula in ano, 6 per cent, and other diseases, 9 per cent.

Although pilonidal cyst is anatomically not a proctologic disorder, it has been customarily studied and treated by proctologists in many parts of this country and abroad and is usually included in textbooks on proctologic disease. A pilonidal abscess is frequently mistaken for a perianal abscess and for that reason is often referred for proctologic care.

## Pilonidal Cyst

Probably the lesion that is of most interest to the military surgeon is the sacrococcygeal or pilonidal cyst. It is interesting for two reasons. First, the military surgeon is struck with the large number of cases he sees in the army in comparison to civilian life, and, second, by the prolonged hospitalization which many of the patients require before being able to return to duty status.

It was observed by Bacon<sup>1</sup> in a series of 268 cases of pilonidal cyst that 93 per cent of the cases were found in persons between 16 and 40 years of age and that 62 per cent of the patients were between 21 and 30. Of all his cases 66 per cent were in the male. All of our cases fall in the high percentage age group and they are all men.

It has been shown<sup>2</sup> from histologic studies of

human embryos that a pilonidal cyst is derived from skin ectoderm by a process of ectodermal invagination in the third and fourth months of embryonic life, in cells which are destined to form hair and glands. This method of origin, plus the analogy drawn between the preen gland in birds and the pilonidal sinus, suggests that the sinus represents a vestigial skin appendage developing at puberty, therefore, the age distribution is at, or slightly later than this period.

Hair protruding from the sinus opening is commonly seen, as is a collection of skin detritus and sebaceous material. This makes an excellent culture medium for organisms to grow upon, and if we add to this surrounding tissue which is devitalized by trauma we have the stage set for an infected pilonidal cyst, or a pilonidal abscess.

The soldier in his everyday life is subject to trauma in this area much more commonly than he would be in civilian life, particularly since the advent of mechanized warfare. Probably the worst offender among mechanized equipment is the jeep. Buie recently read a paper on pilonidal cyst before the Southern Medical Association in which he referred to it as "jeep disease."

The surgical treatment of pilonidal cyst is still controversial, opinion is divided whether to close the wound primarily, pick it open, or do a partial closure plus packing. We will not go into a discussion of the pros and cons of any one type of treatment, as we have not studied a sufficiently large series of cases done by any one method to draw any conclusions. It should be stressed, however, as has been repeatedly cited by the adherents of primary closure, that the success of this type of treatment is directly dependent upon basic surgical principles, namely, accurate hemostasis, complete obliteration of dead space, and mobilization of tissue sufficient to prevent tension on sutures. If these conditions are met it is our feeling that many more of these cases can be dealt with in this manner successfully and the patient's hospital days reduced materially. As army surgeons we are anxious to return the patient to duty as quickly as possible without endangering his health and in such physical condition that he is able to perform his regular job.

Waldenberg and Sharpe<sup>3</sup> studied 100 consecutive cases of pilonidal cyst admitted to an army hospital and treated them all by excision and primary closure. Ten per cent of their patients had had previous excision and 38 per cent had had previous incision and drainage per-

formed. In addition to meeting the basic surgical principles previously suggested, they outline a program of preoperative treatment focused upon elimination of as much inflammatory reaction as possible, plus rigid postoperative management with special emphasis upon local and systemic use of sulfonamides. They stress, in this postoperative period, the fact that frequent dressings invite local infection and there must be a good indication, such as temperature elevation, or local pain out of proportion to the usual incisional discomfort, before the original dressing is disturbed in the first week following surgery.

Their patients have had healed wounds in an average of twenty-one and a half days and are returned to full military duty in an average of twenty-eight days. The incidence of wound infection with breakdown is low in their series.

In using sulfonamides Scott<sup>4</sup> adds the suggestion that the buffered crystalline sulfanilamide containing 10 per cent calcium carbonate will further cut down the percentage of postoperative wound infections. He presents evidence that the anion of the sulfonamides is the agent that is directly responsible for the antibacterial effectiveness of the drug and the difference between the various sulfonamides is based directly upon their acidic dissociation and, indirectly, upon the pH of the wound.

Primary closure may not seem warranted because of the size of the cyst, the presence of multiple side tracts, where a considerable block of tissue will have to be excised, or the presence of considerable infection. The procedure of choice, then, is block excision with undermining of the skin edges to increase the mobility and the use of the method that obliterates dead space and more closely approximates skin edges without a true primary closure, namely, suturing the skin edges to the sacrococcygeal fascia, with interrupted silk sutures as used by MacFee<sup>5</sup> in 230 cases with a very high percentage of cures. The length of hospitalization was not stressed in this series but in our hands it seems to compare favorably with cases of primary closure.

We feel that a lower percentage of recurrences will be seen if each case is carefully evaluated, if considerable attention is paid to preoperative preparation, and the operative procedure is selected to fit the individual indication.

## Hemorrhoids

The most common pure proctologic disorder treated in our hospital is hemorrhoids. We choose to discuss it second only since this type of case does not require as long a hospital stay as the case of pilonidal cyst. It is an important entity for the consideration of the military surgeon because next to infections and fractures of

the extremities this entity accounted for the largest number of admissions to our surgical service of any one lesion in the period previously mentioned.

Smith<sup>6</sup> found in a large series of cases that the sex incidence of hemorrhoids is 2 to 1 in favor of men and that most cases are in the age group of 20-60, with those in the period between 20-40 predominating. Again our cases fall well within these two groups.

The cause of hemorrhoids has been an often debated subject, but as a predisposing cause Montague<sup>7</sup> has shown there is a structural weakness of vascular tissues which is inherited. Forty per cent of our cases gave a family history of hemorrhoids in the same or the preceding generation and the vast majority of these individuals gave a history dating their rectal complaints prior to their entrance into the army. From this we deduce that the increased activity in service did not contribute to the formation of hemorrhoids.

Constipation as a cause of hemorrhoids was practically absent in our cases. Most patients have reported a marked improvement in bowel habits since induction and it is thought, with the improvement in the physical condition of the man plus the rigid adherence to a regulated way of living, that the bowel function and bowel habit had greatly improved.

Probably the greatest single exciting cause of hemorrhoids is inflammation in and around the anorectal line as has been so well described by Buie.<sup>8</sup> He has shown that the first step is a cryptitis due to some type of trauma to the anal crypts with an extension of the inflammatory process to the adjacent structures and invasion of the venous wall with the formation of a typical phlebitis. The pathologic process within the vein wall leads to dilation and a varicosity develops with replacement of the elastic layer by fibrous tissue.

Hill demonstrated, by a remarkable study of hundreds of sections of the anorectal region, the presence of many perianal tubules opening into the crypts of Morgagni, and it is reasonable to assume that infection in the crypt will follow rapidly into these tubules and set up thrombosis in the already congested veins. The continued trauma of daily bowel movements is sufficient to lead to a vicious cycle.

It may be argued that the hemorrhoids come first, and the infection is secondary to stasis. If this is true, it is probably seen only in patients with a definite hereditary history. Even in these cases infection may cause an early breakdown of the hereditarily weak venous structures.

Other factors, such as the absence of valves in the superior hemorrhoidal vein with the hydro-

static pressure exerted by the column of blood from the heart down, increased intra-abdominal pressure from constant straining at stool, heavy lifting, or chronic coughing, or impaired portal circulation from hepatic cirrhosis or cardiac decompensation must be considered in discussing the cause of hemorrhoids, but only a small percentage of cases fall into this group in large series of cases studied in civilian life, and we have found no such cases in this series.

The majority of our cases were of the combined external and internal type of hemorrhoids. We have not included any of the cases of the thrombotic external variety, as they were all treated as outpatients and did not require hospitalization. They were treated with excision of the clot and suture of the skin edges with resulting primary union without suppuration in all cases.

It has been rare in our experience to see simple internal hemorrhoids in the army which could be treated as ambulatory cases by the injection method. Whether the soldier does not report on sick call until he develops a more alarming rectal symptom than occasional bleeding at stool or not we do not know, but that has been our supposition, in view of the large percentage of cases that we see that have to be treated surgically.

We believe that the treatment of external-internal hemorrhoids is surgical excision and that the technic varies with the individual case. Because of the frequent occurrence of associated lesions, such as infected crypts, hypertrophied papillae, fissures, fistulas, etc., no one technic is applicable to every case. The majority of our cases were not associated with much prolapse of the rectal mucosa because they occurred in the younger age group and were treated by the ligation and dissection method with transfixion of the pedicle to the fibers of the external sphincter ani muscle as described by Swinton.<sup>9</sup> These patients were hospitalized for ten days, after which they were returned to duty. After the first twenty-four hour postoperative period they were treated as ambulatory patients. The patients with severe prolapse were considered to be best adapted to the plastic amputative type of hemorrhoidectomy advocated by Buie. The period of hospitalization for this type of case was slightly longer, but they were routinely returned to a duty status at the end of fourteen days.

All of the patients who were on duty in the immediate vicinity were seen at weekly intervals for a period of four to six weeks after being discharged from the hospital so that gentle dilation could be performed to prevent postoperative bridging with infection and stricture formation. Those who were itinerant were instructed to report to the medical officer in charge of their

outfit for such treatment. We firmly believe that this postoperative observation is essential to obtain good end-results and prevent complications following hemorrhoidectomy.

### Abscess and Fistula

Anorectal abscess and fistula, which are different stages of the same inflammatory process which takes its origin at the anorectal junction, will be discussed together.

It is commonly thought that the abscess originates from an infected crypt with an extension of the inflammatory reaction through the perianal tubules to the ischioanal or supralelevator spaces. We have seen many cases of cryptitis associated with hemorrhoids, but the fact that our patients had no general debility and possibly were able to keep the infection well localized, may account for the lower incidence of abscess and fistula formation.

We have seen no case of abscess or fistula secondary to rectal involvement by lymphopathia venerea.

Our cases of abscess were all drained as soon as they were seen and the fistulas were excised after the inflammatory reaction had completely subsided. In most cases the soldiers were discharged to duty for a period of six weeks to two months before the fistulectomy was performed. It was found that if they were seen at weekly intervals to prevent the abscess' reforming the tract was well defined and easily excised at the end of this period with a minimum amount of tissue sacrificed.

### Proctocolitis

During the twelve months covered by this study we have been fortunate in being able to examine a large number of civilian applicants for induction into the armed forces from a very large induction center, who gave a history of colitis. These patients were all subjected to a proctosigmoidoscopic examination and it has been extremely interesting to note that a very small percentage of the patients presented any pathology in the bowel wall indicative of an inflammatory or an ulcerative process. Those patients in whom there were no evidences of inflammation or signs of pathology above the reach of the sigmoidoscope must fall in the groups of so-called spastic colitis, mucous colitis, or irritable colon.

The history was always the same and was that of intermittent attacks of frequent bowel movements, usually four to seven daily, associated with abdominal cramps, lasting for varying lengths of time and usually connected with some emotional strain of varying intensity. There was seldom a history of rectal bleeding associated.

While we do not know definitely how many

of these patients were inducted into the Army, since we saw them only in consultation, we assume that a large proportion of them became soldiers.

During this period we have had only four cases of colitis in 2,500 admissions. Two of these were cases of chronic nonspecific ulcerative colitis and two were the result of old cases of amebic dysentery with negative stool cultures but permanent changes in the bowel wall.

It is interesting to speculate what has become of that group who entered the army with the complaints of diarrhea. Either the complaints were never really severe enough to incapacitate them, or the change of habits and environment, with plenty of fresh air, sunshine, and a well-balanced diet, as suggested by Hurst,<sup>10</sup> have alleviated their symptoms.

### Discussion

Dr. Descum C. McKenney, *Buffalo*—It would seem that the theory that pilonidal sinuses and cysts are due to embryonic invagination of the ectoderm has the largest number of followers, as sections made of them would indicate.

This war has brought together thousands and thousands of our young men, whose duties are strenuous and tend, through injury, to cause infection in these congenital deformities.

From camps scattered all over the United States these diseased individuals in sizable groups are sent to hospitals for treatment and this segregation of this particular disease has provided exceptional opportunity for mass study as to treatment such as has never occurred in private practice and from which, in consequence, the disease is now practically removed.

Previous to our military mobilization the treatment which was most generally accepted and was quite satisfactory so far as end results were concerned was excision and healing by granulation. Except for the first few days of convalescence it did not, in most cases, prevent the individual from carrying on his usual occupation while the wound was healing.

In the military service, however, the wound must be healed, I understand, before the patient is returned to full duty, which created an immediate demand for quick and solid healing to save man-hours; hence, with this object in view, everywhere efforts were at once directed toward improvement of the immediate suture technic. Much has been accomplished and, from the great number of papers that have appeared in the past two years, one gleams the following valuable points, to mention only a few, as practiced by different surgeons in often only slightly modified form:

1. Preoperative elimination of active infection.
2. Meticulous block excision of the diseased tissue without spilling into the wound infection therefrom.
3. Perfect hemostasis.
4. Elimination of all dead space in wound closure by

(a) Undermining wound edges to permit their accurate approximation without tension and then suturing them down to the fascia, with closure of the more superficial part of the wound with vertical mattress sutures.

(b) By the formation from nearby tissues of a central ridge over which the wound edges can be brought together without tension.

Another method, a partial closure technic, attaches the skin edges to the fascia but leaves an exposed vertical midline cleft between to heal by granulation.

Captain Alford, with his experience as a proctologist, recognizes the fact that external hemorrhoids are practically always associated with internal hemorrhoids as well as many other lesions such as fissures, chronic cryptitis, and papillitis, etc.; that the treatment is surgical; and that, for success, all the lesions present must be dealt with at the same operation.

In the surgical treatment of fistulas, failures, such as recurrence and incontinence, are frequently due to attempts at treatment while they are in the abscess stage. As the author has indicated, it is safer to be sure that the offspring of an abscess is really a fistula before treating it as such.

### ASSOCIATION OF MEDICAL COLLEGES TO MEET

The fifty-fifth annual meeting of the Association of the American Medical Colleges will be held in Detroit, Michigan, October 23, 24, and 25, 1944.

Headquarters will be in the Hotel Statler, and the host will be the Wayne University College of Medicine.

# TWO-SCORE YEARS OF PEDIATRICS

## A History of the Pediatric Section

T. WOOD CLARKE, M D, Utica, New York

TWO score years ago pediatrics as a specialty was in its infancy. It is doubtful, if, at the turn of the century, there were a dozen physicians in America devoting themselves exclusively to the care of children. Few medical schools had a teacher of pediatrics and the schools that did made him subservient to the department of internal medicine. If hospitals had children's wards they usually held a few orthopedic cases and little else. The attitude of the public was that if an adult were ill a good doctor must be called, if the children were sick anybody would do for them. A few ambitious young physicians crossed the ocean to learn something about infant and child care in the great children's hospitals of London, Berlin, Vienna, or Paris. The rest got their pediatric education largely from the agents of the proprietary infant-food companies.

Diphtheria, though the mortality rate had been reduced by Behring's discovery of antitoxin, was still the most dreaded of the contagious diseases, tuberculous adenitis, arthritis meningitis, and peritonitis were common diseases, while cases of congenital syphilis, scurvy, and rickets were seen every day.

Cholera infantum, which raised the infant death rate in the summer months to anywhere between 250 and 500 deaths per thousand births, ran the physicians ragged during the months of July, August, and September, and enriched the undertakers, was considered to be an uncontrollable act of the Almighty. We did not then know that it was simply dirty milk poisoning.

Those whose memories go back to the last decades of the nineteenth century can call to mind pictures which would indeed astonish the younger generation of today. There is the filthy, dark cow-barn, the cows plastered with manure and wallowing to their knees in much the farmer with foul hands milking into rusty or dirty pails, the warm milk standing for hours exposed to the sun, the open containers the roosting place of barnyard fowls, with the steady procession of flies buzzing blithely from the nearby privy to the open milk cans. We see the slow trip to the city, the cans rattling noisily as the milk-cart labors through mud to the hubs, and the driver getting out to lift the wheels bodily out of the mudholes. Bespattered and dirty, the cart

and driver arrive in the city. In the same dirty condition he ladles the warm, well mixed milk into his pail, and with a cheerful face and happy song swings up the alley and, fishing the much used and grimy tickets out of the flat milk pan on the back porch, measures out his two quarts and a pint and leaves it open to absorb the rays of the rising sun and wait at the housewife, three hours later, to the great delight of the neighborhood dogs and cats.

Those were the days when milk had to be delivered twice a day in summer, as the morning's milk was always sour by supper time, and if there were a thunderstorm in the morning, it was sour by noon. If the milk had a fair cream content and a good rich cowy odor we were satisfied. We did not know that the cowy odor we so admired was the stench of the manure which the milk contained. The only examination made by the milk inspectors was to take the specific gravity and estimate the cream content to see that it was not watered or skimmed. When bacterial counts were first introduced it was found that the germ content of most of our milk was far higher than that of our sewage. The only measure taken to prevent cholera infantum in the hot weather was to swathe the long suffering infant's abdomen in many layers of wool—the hotter the weather, the more the wool and the unhappier the child.

Although the general medical and lay ignorance as to the cause of the intestinal diseases of children was abysmal, a few voices were heard crying in the wilderness. In 1885 von Guens, of Amsterdam, made the first bacterial count of milk, while the next year pasteurization was born when Soxhlet stated that if milk were heated to 60 C it was less harmful to infants. In 1888 Dr. Augustus Caille, in a paper read before the New York Academy of Medicine, recommended that all milk fed to babies be sterilized. In 1889 Dr. Henry Koplik opened the first dispensary for sterilized milk in New York. In 1892 Budin, in Paris, introduced consultations for infants and Dr. Henry L. Coit, of Newark, became the father of certified milk.

In 1893 Mr. Nathan Straus, of New York City, began his crusade which, during the next quarter of a century, did more for the safeguarding of babies against contaminated milk than any other single factor. In that year, under the advice of Drs. Abraham Jacobi and Roland Freeman,

he opened his famous pasteurized milk stations in New York, one year before Dufour inaugurated his "Goutte de Lait" in Paris. The Straus milk depots demonstrated conclusively that babies who were fed pasteurized milk remained healthy during the summer while those who did not patronize the depots had as much intestinal disease as before. For two score years Straus appealed to the governments of cities, states, and nations, inveighing against the sale of dirty milk and demanding universal pasteurization. His first great victory came after fifteen years of untiring effort when Chicago, in 1907, passed a law requiring the pasteurization of all milk from herds which had not been tuberculin-tested. Five years later New York City required all milk sold in the city, except certified milk, to be pasteurized. Straus not only advocated the municipal pasteurization of milk but presented pasteurizing plants to cities in both America and Europe where the authorities were willing to adopt his ideas but could not afford the equipment. With the spread of municipal pasteurization summer diarrhea in infants faded from the picture. The younger members of the profession have no conception of the once-dreaded cholera infantum.

From 1900 on New York City took an ever increasing interest in the welfare of infants, an interest which led to the organization of the New York Milk Committee in 1906 with its many infant welfare stations and the formation, in 1908, of the Division of Child Hygiene of the Department of Health under the able direction of Dr. S. Josephine Baker.

So startling was the improvement in the health of New York City's infant population under the stimulus of the reforms introduced by Dr. Baker that the movement spread like wildfire through the State and the nation. By 1912, under the stimulation of the enthusiasm of Dr. Goler, Health Officer of Rochester, and Dr. Henry L. K. Shaw, of Albany, Consultant in Child Hygiene of the New York State Department of Health, the interest of the upstate cities was aroused. In that year the Baby Welfare Committee of Utica was organized with one milk station and one nurse for two months in the summer. From these small beginnings have grown the elaborate system of welfare stations which now, either under private or public auspices, care for the infants and educate the mothers in every city in the country.

This awakening of the lay mind to the need of more adequate methods for the care of infants and children which occurred during the first two decades of this century was due partly to the increased social-mindedness of the nation at large, but probably more to the rapid growth of pediatrics as a specialty. The number of men de-

voting their time largely or exclusively to child care increased rapidly. The American Pediatric Society was formed; local and state organizations appeared all across the country, enthusiastically emphasizing the importance of pediatrics as a specialty. The education of the medical profession pediatrically had begun. In 1913 the Medical Society of the State of New York first recognized pediatrics as a specialty.

For over one hundred years the State Society had been holding its annual meetings. As, during most of its life, every physician was a general practitioner, each member of the Society was interested in all papers read and all sessions of the Society were attended by the entire membership. By 1911 the number wishing to read papers had increased to such an extent that in that year the sessions were held for two days, morning, afternoon, and evening, at which forty-four papers were read. By the end of the meeting we were all exhausted and the specialists who had been obliged to listen to forty-four papers in order to hear one or two on the subjects in which they were interested were thoroughly bored. The result was that the next year, 1912, under the administration of Dr. Wendell Phillips, the first steps were taken toward the modernization of the State Society. Besides the general sessions there were five special sections, each of which held four meetings. In the section on medicine thirty-seven papers were read; in that on surgery, thirty; in mental and nervous diseases, twenty-six; in public health, thirty-three; and in eye, ear, nose, and throat, twenty-nine—or one hundred and fifty-five papers in all. Each section produced nearly as many papers as the entire society had done the year before.

At this meeting at Albany in 1912 a notice was posted inviting all men interested in pediatrics to a luncheon. At this time, under the leadership of Dr. Henry L. K. Shaw, a resolution was passed petitioning the State Society for a section on pediatrics. The petition was acted upon favorably and, in 1913, the section on pediatrics came into being, with Dr. Shaw as chairman and Dr. Thomas S. Southworth as secretary. As the section was only provisional and its continuance was dependent upon the success of this first meeting, the officers exerted themselves to the utmost to collect a galaxy of pediatric talent on the program. In all, there were twenty-three papers. Dr. L. Emmett Holt spoke on the then comparatively new procedure of the Wassermann test in its relation to children. Dr. Kerr spoke on hemorrhagic diseases, Dr. Mercer on recurrent vomiting, Dr. Sherman on goat's milk feeding, Dr. Snow on x-ray diagnosis of intussusception, Dr. Pisek on the general subject of infant-feeding, Dr. Van Ingen on infant mortality,

Dr Vander Bogart on enuresis Dr Wynkoop gave a plea for the more frequent use of lumbar puncture, then a procedure rarely used by the general practitioner Dr Leo-Wolf spoke on the care of the newborn, Dr Frost on nursing, and the present writer gave his ideas on the training of sick children Of the twenty-three men who presented papers at this meeting I believe that Drs Wynkoop, Roby, Kerr, Van Ingen and I are the only ones now living

Dr Pisek, in his paper, drew a picture of the status of the infant feeding problem at that time which is worthy of quotation He said that during the past fifteen to twenty years there has been accumulating a mass of knowledge concerning infant feeding which has not been digested and assimilated by the medical profession as a whole Too often a new contribution to this subject has been hastily seized upon and made the basis of a so-called system of infant-feeding instead of being assigned to its relative position in the general scheme of infant-feeding

"At one time sterilization of milk to destroy all the bacteria was lauded as a solution of all infant-feeding troubles, then modified or humanized milk came along, followed by pasteurization Later came percentage modification, for which were offered tables by which infant feeding was to become a mathematical science, then milk and gruel mixtures, whey and cream mixture, malt soup, precipitated casein and maltose mixtures had their advocates Clean milk which contained so few bacteria that it need not be heated was put on the market, and the other extreme, the addition of millions of bacteria to each teaspoonful of milk for the infant's use, was advocated to make it suitable for digestion

"Babies have survived all these fashions and in spite of them the death rate has declined"

The members of the section that year and for a number of years afterwards were tendered an invitation to attend the Tri-city Pediatric Meetings held annually in Boston, New York, or Philadelphia Many of us took advantage of this each year and thus widened our knowledge of and acquaintance with the pediatricians of the neighboring states With the formation of the American Academy of Pediatrics and its sectional meetings these meetings were given up We also, in the early years of the section, held clinical days in the autumn when many of us went to New York City to attend special clinics arranged for us by our New York City members The older members of the section remember these two annual trips with great pleasure We recall especially the debts we owed to Drs Pisek and Dennett for the time and effort they expended in arranging the clinical days in New York City

The following year, 1914, when Dr Southworth was chairman, the number of sessions of the section was reduced from four to three and fifteen papers were read, more time being allowed for discussion The outstanding feature of this meeting was the address of Dr William H Park, describing his great new discovery of the value of toxin-antitoxin in the prevention of diphtheria, the procedure which, since that eventful day, has changed diphtheria from the most dreaded of all diseases of children to a medical curiosity Other prominent contributors to this meeting were Drs Holt, Freeman, Carr, and Keiley

In 1915 the chairman, Dr Joseph Roby, of Rochester, inaugurated the custom of having eminent pediatricians from outside of the state as our guests Dr John Lovette Morse, of Boston, gave a general discussion of digestive disturbances, and Dr John F Sinclair, of Philadelphia, introduced us to the use of the soybean as a milk substitute or diluent in infant feeding The custom was also started of making trips to places of interest in the neighborhood As the meeting was held in Buffalo, we visited the Franklin School, the Park School, and the Fresh Air School, something of an innovation at that time

When Dr Sherman, of Buffalo, served as chairman for the Saratoga meeting in 1916 an important symposium was held on the medical examination of school children, a branch of pediatrics which had been, up to that time, generally most inadequately carried out

When the society met in Utica in 1917, under the chairmanship of Dr Wynkoop, we were introduced to an entirely new branch of medicine which has grown with tremendous strides in the last quarter century, has been of intense interest to pediatricists, has developed a complete new specialty, and now has an American College for those who practice it When Dr Fritz Talbot, of Boston, read us his epoch-making paper entitled 'The Role of Idiosyncracies in Practice' he gave to us our first knowledge of allergy

On the last day of the meeting we visited the New York State School for the Feeble-Minded, in Rome, where Dr Bernstein and his staff and Dr Cornell of Albany demonstrated to us the various types of mental deficiency

At the 1918 meeting at Albany, at which I had the honor of presiding, we had a joint meeting with the section on obstetrics Dr Hirst, of Philadelphia, discussed birth injuries and Dr J P Crozier Griffiths of the same city spoke on the maintenance of breast-feeding The latter's plea for breast-feeding contained so many truths which seem to have been forgotten in these days of four-hour nursing and immediate supplemental

feeding that some quotations are of interest. He emphasized the fact that "nothing will so soon diminish the milk supply as the insufficient emptying of the breast and nothing, on the other hand, conduces so greatly to an increase in the secretion as the increase in the demands made upon it." Later he said that "the average normal infant empties his stomach in one and a half to two hours and is then ready for more." "The longer the interval, the less stimulation of the breast occurs and the greater the danger of the milk supply's diminishing." He assured the section that "even a little breast milk is much better than none, and this is particularly true in the first three months of life." At the present day, when the newborn baby is nursed every four hours or not at all, and his appetite is sated with a milk formula from the hour of birth, the mother who nurses her baby for more than two weeks has become rare enough to put in a museum.

On the last day of this meeting we adjourned to the Hudson Reformatory, where Dr. Lewellys Barker, of Baltimore, spoke on the nervous, spoiled child, and Dr. Healy on "The Cause and Prevention of Delinquency."

The Syracuse meeting of 1919, under the chairmanship of Dr. Vander Bogart, stressed, for the first time before the section, the child welfare movement then rapidly spreading across the country. Miss Julia Lathrop, director of the U. S. Children's Bureau, described the work of the organization and Drs. Hamil, of Philadelphia, Richard Smith, of Boston, and Shaw, of the New York State Department of Health, discussed the procedures in their localities.

When we met in New York City in 1920, under the chairmanship of Dr. Mercer, we were introduced to another epoch-making advance in medical knowledge, the vitamins. Dr. Hess, of New York City, discussed the antiscorbutic vitamins, Dr. Osborn, of New Haven, discussed the water-soluble vitamins, and Dr. Mendel, also of New Haven, spoke on the fat-soluble vitamins. These were all the vitamins known at that time. It is of interest, in view of the tremendous vogue today for swallowing vitamin pills for all conditions from dandruff to ingrowing toenails, to see what Dr. McCollum, of Johns Hopkins, the leading authority on vitamins, said at that time in his discussion of these papers. "I regard it as a step in the wrong direction to give the medical profession the idea that there may be expected marked therapeutic effects from commercial preparations of vitamins such as are now on the market from a number of sources."

In a joint session with the section on public health, Dr. Allen Kraus, of Baltimore, said that 10 per cent of the people who have tuberculosis

develop it in their first year, 30 per cent by the end of the third year, 60 per cent by the sixth year, and 75 per cent by the time they are 15. He believed the large percentage of childhood infections was due to children's playing on tuberculosis-infected sidewalks.

In the Brooklyn session in 1921, under Dr. Ludlum, the chief features were another joint session with the section on public health, an appeal by Dr. Haas against the puncturing of the ear drum, and pediatric clinics at the Brooklyn Hospital.

In 1922, in Albany, when Dr. La Fetra was chairman, we had a further discussion of toxin-antitoxin and the Schick test by Drs. Zingher and Park, a paper on status lymphaticus by Dr. Walter Timme, an appeal by Dr. Haynes that pediatricists be on the staff of obstetric hospitals and that all babies be transferred to their services on the day of birth, a visit to the State Laboratory, and to a clinic at the Troy Day Nursery.

Periodic examination and universal toxin-antitoxin immunization featured the 1923 meeting in New York under Dr. Bartley, with Dr. Richard Smith, of Boston, Dr. Zingher, of New York City, and Dr. Florence McKay, director of the Division of Child Hygiene of the State Department of Health, as the speakers.

In Dr. Card's session at Rochester, in 1924, we had an exceptionally large number of distinguished visitors, including Dr. Bela Schick, of Vienna, Dr. Oliver Kimball, of Cleveland, Dr. Abt, of Chicago, Dr. Alan Brown, of Toronto, and Dr. Park, of New Haven.

Again in 1925, at Syracuse, the chairman, Dr. Joseph Palmer, brought us many visitors. Dr. Mason Knox, of Baltimore, discussed periodic examinations of children, Dr. Thom, of Boston, spoke on mental hygiene, Dr. Helmholtz, of the Mayo Clinic, read a paper on ulcerative colitis, and Dr. Herrick, of Chicago, discussed the chronic cardiac cripple.

When we met in New York City, in 1926, under Dr. Roger Dennett's chairmanship, the new discoveries in scarlet fever were discussed by Drs. Dochey, Park, and Zingher, of New York City, and Dr. Blake, of New Haven, and Dr. McCollum, of Baltimore, gave us the latest discoveries in vitamins.

Since 1927 the chairmanships of the section have been held by Drs. Benson, Donnelly, Leo-Wolf, Aikman, Pease, Kaiser, Doust, DeSanctis, Sincerbeaux, Retan, Williams, Craig, Beaven, Arnold Hawkins, Ashton, Orr, and, now, Dr. Silverman. In 1930 the number of sessions of all sections was reduced to two, so that since that time our programs have been cut in half, a change which may be an advantage to the general practitioner

but which makes the meetings of less value to the specialist. Time does not permit a detailed report of these more recent meetings, most of which my hearers have attended. We have had many distinguished guests, including Drs Morse, of Boston, Harold Cushing, of Montreal, Grulee of Chicago, Tyson, of Philadelphia, Powers, of New Haven, Roundtree, of Philadelphia, and Hess, of Chicago.

We have been kept well posted on the care of the diabetic child by having as our guest Dr Priscilla White, of Boston, in 1932 and again in 1941. In 1932 Dr Kaiser discussed the value of immune adult blood in the treatment of measles and Dr Dennett spoke on the use of nervinol in chorea. In 1934 Dr Retan brought to our attention his method of forced drainage of the central nervous system and the next year Dr Sauer reported on his method of immunizing against pertussis. In 1936 Dr Gordon reviewed the use of thyroid, pituitary, and pituitary-like substances in hypogonadism and cryptorchidism.

In 1938 we were first introduced to the sulfa drugs when Dr Carey, of Boston, read a paper on the use of mandelic acid and sulfamidamide in urinary infections in children, and the following year Drs Emm and Silverman told of the treatment of pneumonia and scarlet fever by sulfamidamide. In 1940 Dr Calvin, of Chicago, brought before us the routine inoculation with tetanus toxoid as a preventative of tetanus, and the following year Dr Glaser, of Rochester recommended a bovine tetanus toxoid for the same purpose.

From the foregoing it will be seen that for over thirty years the section on diseases of children has served the physicians of New York, pediatricians and general practitioners alike, as a postgraduate school at which those who have attended have had brought to their attention all of the latest discoveries relating to the diseases of children. By its efforts and those of similar organizations throughout the country

the practice of pediatrics in two score years has been raised from a subservient position as a despised adjunct of internal medicine to a division of the medical profession which can stand on its own feet and be proud of its accomplishments.

## Discussion

Dr Edward J. Wynkoop, *Syracuse*—Dr Clarke's review of pediatric history, especially of our Section of the State Society, is very interesting.

To Dr Shaw of Albany must go the credit for forming the Pediatric Section of the State Society. Certainly he was an indefatigable worker, and along with Vander Bogart of Schenectady, Pisek and Van Ingen, of New York, Clarke, of Utica, and Sherman, of Buffalo, was instrumental in getting the section started. These men also made a special effort to get those interested in diseases of children to attend the meetings for several years.

Dr Clarke's mention of the inroads of cholera infantum carries one back to the time when we used to have so much diphtheria in hospitals, especially in the orthopaedic wards. The immunization of children with toxoid has made a great change in the inroads of diphtheria in institutions. It has always seemed to me that Coit had not been given enough credit for the splendid work he did in reference to clean milk. He accomplished so much in his efforts to get good milk, and his certified milk filled a great need.

It seems to me that the Section has been very active and that a great many interesting papers by men from out of the State have been presented at our meetings. This influence, I think, has been felt throughout the entire State in promoting health matters, especially as to the prevention and treatment of diseases of children.

Dr Clarke has referred to breast feeding, it seems to me that pediatricians have not used their influence, nor emphasized sufficiently to the mothers the importance of breast feeding. With the present overflowing of the hospitals, and through the necessity to push the patients out rapidly, many times insufficient efforts have been to promote normal breast milk feedings.

## PATIENTS AS HOSPITAL ATTENDANTS

"Two years ago it would have seemed almost too absurd to think about," says Harry Kromer, R N, chief occupational therapist, "but today at Norwich State Hospital, Norwich, Conn., we are actually using patients as hospital attendants."

Selected patients are referred to the medical staff for approval and are then given a short period of instruction, uniforms, keys, special living quarters and a ticket entitling them to eat in a special dining room.

Starting with a few patients at first, 25 were soon serving. In fact, of them

and others have found jobs outside the hospital. Two discharged patients are now on the hospital's pay roll.

"The incredible part of the whole project," Mr Kromer reports, "is that during this period there have been only three demotions for infractions of the rules."

The personnel director at Norwich is running a full page display advertisement on the back page of the hospital's house organ, the *Stylus*, asking relatives and friends of patients to search out and refer to the hospital anyone who is willing to work full time or part time at the hospital.—*Modern Hospital*, June, 1944.

# RECENT ADVANCES IN STUDYING THE PROBLEMS OF HEALING AND THEIR EFFECT ON THE TREATMENT OF WOUNDS AND BURNS

EDWARD L. HOWES, M.D., New York City

AT THE beginning of this war, certain definite principles were well established for the care of wounds. Listerism was successful in preventing infection in constructed wounds, yet antiseptics were notoriously unreliable for preventing infection in contused wounds and for terminating the established infection. Infection could usually be prevented in contused wounds by cutting away the damaged tissues, if this was done when the tissues were contaminated with bacteria and not invaded by them. If the contused tissues could not be completely cut away, or if the wound was seen after the period of bacterial contamination was passed, then the infection was best treated by drainage, and not by attempting to destroy the bacteria.

Just before the onset of this war, in 1936-1939, sulfonamides were introduced for the local therapy of wounds, and it seemed as if a new era had arrived in the treatment of wounds. Jaeger,<sup>1</sup> in Germany, as early as 1936, had used sulfanilamide locally in a few accidental wounds. Sinclair,<sup>2</sup> a dentist in Canada, had employed it in 1937, and d'Harcourt<sup>3</sup> used sulfanilamide in seventeen wounds in the Spanish civil war (1938). The present writer, in October, 1938, was one of the first in this country to report on the general use of sulfanilamide to prevent spread of infection from wounds.<sup>4</sup> Incidentally, it might be of interest to mention that this report was given in this city at the Waldorf Astoria Hotel. Jensen and his collaborators<sup>5</sup> and Key<sup>6</sup> popularized the local use of the sulfonamides in this country. They treated a large number of compound fractures and soft tissue wounds with sulfanilamide.

By the time of the retreat from Dunkirk, the British Army was using the sulfonamides locally beneath plaster casts, and in the bombing of London, which followed, Henry Heyl<sup>7</sup> described the situation thus: "We were mighty glad to sprinkle sulfanilamide in all wounds. The wounded were covered with dust from head to foot, their clothing was badly torn, and their skins were black with dirt or crusted blood."

Jensen,<sup>8</sup> however, very early warned that, if there was an excessive amount of dead tissue or foreign body present, local sulfonamides would not prevent infections in wounds, and in my own

publication, mentioned hereinbefore, I wrote as follows:

"It must be emphasized, however, that under no circumstances must the toilet of the wound be neglected. The combination of foreign body and dead tissue plus bacteria is a powerful one for producing infection, and can hardly be defeated by the use of drug alone. Too often the local toilet of the open wound is neglected simply because the wound is going to be left open."<sup>4</sup>

This realization, that the use of sulfonamides could not defeat dead tissue, grew and grew until at the battle of El Alamein it was finally reported that 50 per cent of the wounded reaching the dressing stations had infected wounds, although theoretically sulfonamides were dusted in all. This may or may not, the statement reads, be considered a triumph for the sulfonamides, depending on the point of view, for theoretically 100 per cent of the wounds should have been infected.

Later, though, when the statistics began to come in about the wounds treated locally with and without sulfonamides from the various study units set up by the National Research Council under the direction of Meleney,<sup>9</sup> it was definite that the local use of sulfonamides had not defeated the combination of dead tissue plus bacteria. A distinct gain had been made, however, because the sulfonamides were found to be excellent in keeping infection from spreading from the wound.

To recapitulate, then, the introduction of the local use of sulfonamides had not changed the local treatment of wounds, because the sulfonamides could not reach the bacteria within the interstices of dead tissue. Dead tissue within the wound was still the media for the growth of bacteria, as is dead meat in the test tube, and the amount of it, depending on the amount of contusion and loss of blood supply sustained in the injury, determined whether an infection would develop. If dead tissue could be removed early, excellent healing was obtained; whereas, if it could not be removed, drainage and rest, and not the attack on the bacteria, was still the most successful method of treatment. On the other hand, chemotherapy had added a wonderful new chapter to the general treatment of wounds, for infection was kept from spreading from the local site and the individual was not destroyed, even though the local process was not

arrested Those who have followed the work of Florey and Cairns<sup>10</sup> in the field with penicillin can discern that this new antibiotic is encountering the same difficulty with dead tissue, and the same difficulty will be encountered with the many new antibiotics, still to be tried

Let us, therefore, turn our attention to what has been done, and what is being done to rid the wound of dead tissue

Three methods of treatment of wounds and burns have previously been partially successful in dealing with the dead tissue or slough Carrel and Dakin,<sup>11</sup> while attempting to devise a solution which would inhibit the growth of bacteria, yet not destroy tissue, also compounded one capable of dissolving slough Dakin's solution, though, begins to lose this property after forty-eight hours, and furthermore, the chlorine solutions modified after it do not have this capacity to dissolve necrotic tissue They are, in other words, only chlorine antiseptics

In the second method of dealing with slough its protein was converted into an insoluble form on which the bacteria could not survive Thus the skin destroyed by burning was converted into a dry, hard eschar by a coagulant, such as tannic acid This method has been abandoned for the present because all the damaged tissue could not be converted and consequently bacteria were able to establish themselves in injured tissue immediately beneath the eschar Tannic acid also destroyed adjacent healthy cells On the beneficial side, though the eschar furnished by this conversion served as a protective film for the body This film prevented recontamination of the burned area by bacteria and in most instances the formation of a surface weeping excessive amounts of exudate and body fluids, until a proper granulating base suitable for grafting could be formed Because of these many good features, the coagulation technique might still be recalled if the undesirable complications could be eliminated

To show how the fundamental idea of coagulation was distorted, however, let us recall how many films were devised in the first year of this war to place on top of unchanged burn tissue on the theory that a film was what was required These inventions did exactly what was not wanted—namely, to leave the burn tissue unchanged and in a moist environment for the bacteria to grow upon

In the third method, exudate was allowed to puddle on the wound inside a cast or in an infrequently changed dressing, and the slough was liquefied by its contained enzymes Enzymes are also elaborated by certain bacteria, such as pyocyanus This method was reintroduced during the last war by Winnett Orr<sup>12</sup> who, dis-

satisfied with the results obtained with Dakin's solution, immobilized infected wounds in casts The method was extended by him afterwards for the treatment of osteomyelitis It was repopularized again by Trueta<sup>13</sup> during the Spanish civil war (1938) Trueta, as nearly as can be told from the records, worked immediately behind the battle fronts, debrided all wounds thoroughly, and opened up the tissue spaces before applying his casts Many of the wounds treated by him were apparently contaminated and not infected Yet, in spite of this criticism, the method was apparently very successful in his hands and under the battle conditions found in Spain at that time Infection did not spread, complications were few, and his mortality was low The Trueta method employed in this war under different battle conditions has not always been successful An account of some of these poor results and a criticism of the method has been written by the French surgeon H Truchaud<sup>14</sup>

Dealing with slough in this manner is, of course, a return to the days of "laudable pus," regardless of whether the method is being carried out in the form of a cast or as pressure dressings, as employed in the treatment of burns today Valuable lessons have been taught, however, by the immobilization infrequent dressing technique (1) rest helps to limit the spread of infection, and (2) recontamination with new bacteria is definitely harmful Recontamination is more harmful during the exudative phase of healing, when it will prolong an infection or establish a new one, than in the granulating period which follows Granulations act as a barrier to the invasion of bacteria multiplying on the surface of a wound

In our search for new methods to deal with slough, we determined to explore the possibility of using substances capable of dissolving proteins and collagen Dead fascia and muscle require the use of strong acids or alkalis or enzymes to liquefy them Alkalis are useless, because repeated applications cause tissues to become edematous and soggy Acids do not do this Acids cause the fibers of collagen or fascia to plump and to loosen one from the other When plumping and loosening are maximal at a pH of about 2.5, collagen goes into solution Of the many enzymes which dissolve proteins, each one has a definite pH range for its activity, although collectively there is an enzyme available for the entire acid to alkaline range There are also certain auxiliary substances which help enzymes to liquefy collagen

The activity of the enzymes and acids in liquefying proteins and collagen and the conditions pertaining to their efficiency were tested by first estimating their capacity to dissolve

FIG. 1. The square under the metal marker is the area of contact with the cautery. The area of burn slough is within the circle. It is beginning to separate spontaneously on the eighteenth day. The area has not been treated.

FIG. 2. Slough of third-degree burn removed by acid and pepsin in four days. Note that fat in the base and the vessels have normal appearance. The area was filled with granulations by the seventh day.

gelatin on photographic plates and to destroy plain catgut, at body temperature, the strand of catgut being a form of collagen. The following enzymes were tested at the pH of their activity: trypsin, enzymol, ficin, keralin, pepsin, and papain with its various activators—i.e., cysteine, etc. The auxiliary substances tried were urea and sodium salicylate. The following acids were examined: succinic, oxalic, acetic, phthalic, stearic, hydrochloric, mandelic, and propionic.

The capacity of a substance to turn healthy tissue into slough was studied by removing a button of skin and placing two or three drops of the agent either on the subcutaneous tissue containing blood vessels or on exposed muscle. Immediate changes were observed as well as those occurring twenty-four hours later. Obviously, the substance employed should not create slough, for it would be pointless to replace slough with slough.

Sloughs were then created by burning the skin of rabbits with an electric cautery (Figs. 1 and 2) at 250 F. for one minute. The times required for the various agents to remove this dead piece of tissue were compared with the times required for unaided separation. The time when the granulations first appeared thereafter was noted (Chart 1). Finally, the capacity of the agent to hinder the rate of regeneration of tissue was

evaluated on a standard wound preparation devised for this purpose.

As a result of these tests, it was found that slough could best be separated without creating more slough and without interfering with the subsequent regeneration of tissue by means of pepsin with hydrochloric acid. Other acids—phthalic, succinic—could also be used in place of hydrochloric. These substances could be incorporated into water-soluble bases and still remain active. Sulfadiazine did not interfere with their activity.

While this work was in progress, Connors and Harvey,<sup>15</sup> working in the same manner, tested out a similar group of acids, including pyruvic. They found that the latter, unlike the other acids, separated slough without the help of enzymes. We have also found this to be true, although it did not dissolve catgut, and have further observed that more rapid separation occurred when pepsin was combined with pyruvic acid. Pyruvic acid also worked when combined

with water-soluble bases, and was active in certain concentrations in cholesterolized petrolatum.

The implication of these results for the future treatment of slough is far-reaching. We have had some experience with the treatment of burns with these agents, but the laboratory data have not yet justified their use for the treatment of wounds. In the treatment of burns these agents did not irritate, nor damage normal skin in the concentrations used if they were applied in the proper bases. They were not prohibitively painful. They quickly distinguished third and deep second degree burns from superficial second and first degree burns. They did not convert second degree burns into third. There was less exudation from the burned area. Pus, if produced, was liquefied by acid. Last but not least, slough was separated rapidly, allowing earlier skin grafting. Acidosis has not been produced by the use of pyruvic acid, although the entire leg of an adult has been covered with it in starch paste. This patient, however, received an adequate amount of sodium lactate. Arnold<sup>16</sup> has shown that the number of bacteria in the normal skin is decreased in the presence of acid.

Next, let us turn our attention to the problem of whether wound healing can be stimulated. This possibility has been repeatedly mentioned in the literature, and during this war, we have been forced to test out numerous substances said to stimulate wound healing. Moreover, in the future many more agents of this nature will be proposed, largely because the contained active agent reputedly causes cells to proliferate more rapidly than usual. Therefore, they should hasten the process of healing. Scarlet red, the sulphydryl compounds, balsam of Peru, cod liver oil, Allantoin, and, more recently, bitydne have been used on this basis. Observations have even

CHART 2. Curve of healing of the open wound.

been made crediting them with stimulating wound healing—"25 per cent increase in the rate of wound healing," or "the wounds healed a day or two faster"—have been recorded, yet all these conclusions are false and, actually, wound healing cannot be stimulated. These false conclusions have been reached through the employment of incorrect methods of measuring the rate of wound healing.

The reasons why the methods employed were incorrect are as follows. As the open wound heals, the changes in its size fall into two distinct periods (Chart 2). In the first one, the dimensions of the wound do not change. This period is known as the lag or latent period of healing, and microscopically it is characterized by exudation and the inflammatory changes. During it bacterial invasion is resisted, dead tissue is liquefied, and the field is prepared for the regeneration of new cells. This period is of somewhat shorter duration in young animals than in adults. Although many factors determine its length, the lag period is terminated by the regeneration of new tissue, and yet to date no one has shortened it by the employment of stimulants unless young animals were used inadvertently. On the other hand, the length of this period has been prolonged by many things: by infection, by frequent dressings, by dry dressings, by continuous wet dressings, and by many therapeutic substances.

In the second period, the size of the wound decreases for two reasons: (1) the surrounding healthy tissues contract; and (2) new tissue is regenerated. In the regeneration, granulations fill the depths of the wound while epithelium covers its surface. In most areas of the body, 75 per cent of the closure of a wound is due to contracture of the surrounding uninjured tissue, and hence the resulting scar is usually much smaller than the original wound. Regeneration

FIG. 3. The dark area in the center is the square of skin which produced the white circle of new epithelium about it. The wound, ten days old, was dressed with vaseline gauze. In the first five days there was no regeneration of new tissue, so that this amount of epithelium was put out in five days. The steel marker measures  $\frac{1}{2}$  cm. Considering this magnification; the rim of new epithelium, measuring 2 cm., represents 30 mm. of new tissue produced in five days, or an extension of 0.57 mm. per day.

of tissue alone accounts for the closure only in certain special areas of the body, where the skin is stretched over bony or fibrous structures. Obviously, if a therapeutic substance stimulating cellular proliferation is applied to a wound closing 75 per cent by contracture, the effect will be partially hidden, while, on the other hand, uncontrolled contracture may give a false result.

Mathematically, too, the rates of decrease of square or circular wounds are usually incorrectly compared. When tissue is regenerating at a constant rate squares always close more rapidly at the beginning of the change than at the end. For this reason, when the rate of regeneration of new tissue is changing, comparison becomes so very difficult that the results are usually misinterpreted. It is only possible to obtain straight lines for comparison by abstracting the square roots of the areas and plotting these against time.

Also, the concept of the controlled wound is often in error. Measuring the rate of wound healing is similar to measuring the speed of a race. The best time required to cover a distance or close a defect must be exceeded to set a new record. Stimulation of wound healing means setting a new record, and unfortunately, too often the so-called controlled wound does not exhibit the best rate of healing, but a retarded one. It will be recalled how easily the latent period can be prolonged.

Last, when a method was employed for evaluating the rate of wound healing with these

previous faults eliminated, stimulation of wound healing could not be demonstrated. In this method the wounds were made on the ears of rabbits, where no contraction occurred. The rate of regeneration of new tissue was measured by means of photography. The amount of extension of new tissue was expressed as a unit of time, consisting of the number of days required to overcome the lag period and to produce a definite amount of new tissue: 2 mm. (Fig. 3). This time was taken as an index of healing for the particular substance tested, and the indices obtained with various substances were scored against each other. When the index was low, 2 mm. of new tissue had been produced in the shortest length of time. When the index was high, either the latent period was prolonged or the amount of new tissue regenerated daily was small. Because these wounds were made under antiseptic conditions, it was assumed that if the index was high, either the medicament had no capacity to maintain bacteriostasis, or that the substances destroyed tissue. Many times a bacteriostatic substance which was known not to interfere with healing was added anyway to ascertain whether the test substance detracted from the optimal rate which it produced.

In this way an optimal rate of healing had been obtained with a lag period of 3.5 days and 2.5 days more required to produce 2 mm. of new tissue, to give an index of 6.0. This has been obtained with sulfadiazine, sulfamerazine and sulfasuxidine, incorporated in an innocuous vehicle which did not destroy cells, and which allowed the medicaments to be dispersed to wounds. It must be emphasized that the base itself must not destroy cells. We also obtained this optimal rate when the vehicle had a pH on the acid side.

Most substances applied to wounds, even with sulfadiazine present, did not produce this optimal rate of healing, but detracted from it. Dr. Henry Simms, my collaborator, has demonstrated why this is so.<sup>17</sup> He is able to keep adult cells alive in a piece of tissue removed from an adult animal by bathing it in serum ultrafiltrate. When this piece of tissue is transplanted twenty-four hours later into a satisfactory culture media, the cells proliferate. If a substance is toxic to cells, a very minute amount of it added to the ultrafiltrate will prevent the cells from growing. In every case where Dr. Simms has demonstrated in this manner that a therapeutic substance is completely toxic in minute amounts, we have failed to obtain a good index of healing. This is not always true with moderately toxic substances. Conversely, when the cells were not killed by minute amounts of the therapeutic substance, optimal healing was obtained. This was the

ease with the sulfonamides mentioned. Incidentally, we also failed to obtain a good index of healing when serum ultrafiltrate was employed on the wound, because this substance, which really keeps cells alive, also stimulates the rate of proliferation of bacteria and causes an infection to develop in the wound.

Finally, it must be emphasized that wound healing is a constantly inhibited process. The length of the lag period and the rate of regeneration are prolonged and retarded by many trivial factors. Moreover, these factors are so constant and so manifold that therapy of wounds will find a new era when we lose the concept of trying to stimulate healing and instead direct attention toward trying to remove or correct the inhibitors of their healing. Rates of healing are usually satisfactory when the inhibitors are removed, and even when maximal regeneration of new tissue is a relatively minor space-closing mechanism as compared to contracture. In other words, when the amount of space to be filled is large and contracture has failed or done its work, then either mechanical approximation or transplantation should be employed and the

regeneration of tissue not relied upon. The process of epithelization, for example, possesses a rate which is so slow that if it were stimulated to twice usual capacity, skin grafting would still be necessary to recover most defects.

## REHABILITATION CENTER FOR BLIND

A rehabilitation center where blinded veterans of all branches of the service will receive extensive training in such different kinds of work as stenography, typing, filing, general clerical tasks, metal and wood working, operation of small machines, etc. The center is located in the old building of the Avon School, which was leased from the Old Farm Convalescent Hospital and is under command of Col. Frederic Thorne. The purpose of the center is to give the veterans the maximum benefit of their training in service hospitals, which was leased from the Old Farm Convalescent Hospital and is under command of Col. Frederic Thorne. The purpose of the center is to give the veterans the maximum benefit of their training in service hospitals, which was leased from the Old Farm Convalescent Hospital and is under command of Col. Frederic Thorne.

# TREATMENT OF MENINGITIS WITH PENICILLIN INJECTED INTRAVENOUSLY AND INTRAMUSCULARLY\*

ALISON HOWE PRICE, M.D., and JOHN H. HODGES, M.D., Philadelphia

WHEN penicillin is injected intravenously it is said to accumulate in the spinal fluid in amounts insufficient to be therapeutically effective; hence, intrathecal injection has been recommended. It is uncertain, however, whether or not the presence of penicillin in the spinal fluid is actually necessary to control infection. If the infection involves the meningeal membranes primarily, it would seem that penicillin given intravenously reaches the involved tissues through their blood supply, as it does elsewhere in the body, to exert its effect on the bacteria. Bacteria present in the spinal fluid may represent only those shed from the inflamed membrane, which disappear when the infection is controlled.

Recent consensus deprecates intrathecal therapy for meningitis generally. Spinal punctures should be done chiefly for diagnosis, to determine the effect of therapy and to relieve intracranial pressure. If intravenous therapy with penicillin cures meningitis, there is no need for injecting it intrathecally. Thus far several patients with meningitis have been successfully treated without intrathecal injection, one with pneumococcal meningitis, one with staphylococcal meningitis,<sup>1</sup> and one with meningococcal meningitis.<sup>2</sup>

An opportunity for testing the value of intravenous therapy arose with a patient who had staphylococcal meningitis, but whose lumbar and lower thoracic vertebral tissues were densely calcified from previous osteomyelitis. Rather than inject penicillin intracisternally, it was given by vein. The good result obtained in this case then led to similar treatment with success in 2 patients with pneumococcal meningitis and 2 with meningococcal meningitis. Two deaths occurred, one in a case of pneumococcal meningitis complicating diabetes and one fulminating meningococcal meningitis in a patient with hyperthyroidism.

## Case Reports

*Case 1 (Staphylococcal Meningitis).*—A man, aged 33, had had renal abscess, osteomyelitis of the left forearm and recurrent psoas abscesses between 1930 and 1936, from which he fully recovered. In 1943,

because of pain in his back and legs for six weeks, he entered Jefferson Hospital on October 25, with obvious meningitis. Lumbar puncture could not be made because of extensive regional calcification, but a cisternal puncture revealed cloudy fluid containing 6,000 leukocytes per cu. mm., 95 per cent of which were polymorphonuclear leukocytes, and many gram-positive cocci, which proved to be *Staphylococcus aureus*. Sulfadiazine in doses of 1 Gm. was given every four hours until the amount in the blood reached 10 mg. per 100 cc. Sulfadiazine therapy was maintained for three days, but no significant effect resulted.

Penicillin was then given by the intravenous drip method in doses of 100,000 units daily from November 1 to November 14. Intense itching developed on the fourth day of therapy. The temperature, which had varied from 100 F. to 105 F., gradually diminished and reached normal November 8, eight days after penicillin therapy had been started. The patient, however, was still severely sick and nuchal rigidity persisted. Cisternal puncture on November 7 revealed yellow fluid containing flaky debris, gram-positive cocci, which failed to grow on culture medium, and 42 cells per cu. mm. Because of thrombophlebitis of accessible veins, after November 14 penicillin was given intramuscularly in doses of 2 cc. (8,200 units) every two hours (100,000 units in twenty-four hours), and on November 15, was reduced to 50,000 units in twenty-four hours. By November 22 recovery was well under way, the abnormal neurologic signs had diminished, and the spinal fluid contained only 24 cells, no bacteria, and no growth occurred on culture media. Penicillin was discontinued on November 28, after 1,300,000 units had been given intravenously, and 750,000 units intramuscularly (total 2,050,000 units).

*Case 2 (Pneumococcal Meningitis).*—A white girl, aged 3 months, was admitted to the hospital December 30, 1943, having been sick for three days. She did not eat, had fever, with a temperature of 103 F., and vomited occasionally. There was a staring gaze, the head was rotated to the left, and there was slight nuchal rigidity. The leukocyte count was 6,000. The spinal fluid was turbid; it contained many polymorphonuclear leukocytes, and type III pneumococci. Blood cultures showed no growth. The patient was given sulfadiazine orally for eight days, but failed to improve. On the eleventh day of illness, penicillin was started. She was given  $\frac{1}{2}$  cc. (2,000 units) of penicillin intramuscularly every hour for twelve hours, or 24,000 units; and  $\frac{1}{2}$  cc. intramuscularly every two hours thereafter; that is, approximately 2,000 units of penicillin every two hours, a total of 24,000 units in twenty-four hours. The patient's temperature dropped to 99 F. on the seventeenth day and became normal on the twenty-fourth day of illness.

\* The penicillin was provided by the Office of Scientific Research and Development from supplies assigned by the Committee on Medical Research for clinical investigations recommended by the Committee on Chemotherapeutic and Other Agents of the National Research Council.

From Jefferson Medical College and Hospital, Philadelphia.

spinal fluid cultures were sterile and penicillin was stopped on January 31, 1944. The patient was discharged on February 14.

The total amount of penicillin given was 530,000 units intramuscularly in twenty-four days.

**Case 3 (*Pneumococcic Meningitis*)**—A colored woman, aged 36, a mild diabetic, was admitted to the hospital February 10, 1944, with a history of a draining left ear for two weeks and a severe headache for forty-eight hours. Physical examination revealed sluggishly reacting pupils, drooping of the posterior wall of the membranous portion of the aural canal, nuchal rigidity, fever, with a temperature of 102 F, and bilateral Kernig's and Brudzinski signs. The spinal fluid was turbid, it contained 9,000 cells per cu mm, mostly polymorphonuclear leukocytes. Type III pneumococci were present in the spinal fluid, and in the discharge from the ear and from the nasopharynx.

The patient was given penicillin, 100,000 units daily, by continuous intravenous infusion. The temperature returned to normal on the fourth day of treatment and on the seventh day the daily dosage was reduced to 50,000 units daily and continued for six days. On March 3 the patient was symptom-free and was discharged on March 7, 1944.

The total amount of penicillin given was 1,000,000 units intravenously by continuous intravenous infusion, over thirteen days.

**Case 4 (*Meningococcic Meningitis*)**—A colored boy, aged 5, developed a typical case of meningitis on January 23. On January 25, he became stuporous and at the time of admission to the hospital had a temperature of 103 F, pulse 120, and respirations 32. Physical examination showed nuchal rigidity and bilateral Kernig's sign. The spinal fluid was under increased pressure and contained 2,000 cells per cu mm, 95 per cent of which were polymorphonuclears. The stained smear showed occasional gram-negative diplococci, and *Neisseria meningitidis* was cultured from the spinal fluid. The blood culture showed no growth.

Penicillin was begun on January 25 at 2:00 P.M. The patient received 25,000 units of penicillin in 1,500 cc of physiologic saline solution by continuous intravenous infusion, in twelve hours. After 2:00 A.M. on the following morning, January 26, 4,200 units of penicillin were given every two hours intramuscularly. The temperature became normal sixty hours after the penicillin was started. Spinal fluid secured on January 29 showed 18 cells per cu mm, predominantly polymorphonuclear leukocytes, no organisms in the stained smear, and no

growth of his neck. Physical examination revealed nystagmus, unequal pupils, and nuchal rigidity. Kernig's sign was positive bilaterally and there was a positive Brudzinski sign. The leukocyte count was 20,000. Blood culture showed no growth. The spinal fluid was cloudy and contained many gram-negative intracellular diplococci, the cell count was 6,000 per cu mm.

Penicillin was given by continuous intravenous infusion in 100,000 unit dosage every twenty-four hours for five days. Spinal fluid was sterile thirty-six hours after beginning treatment. A neurologic examination on February 25 was normal and the patient was discharged on February 29, symptom-free. A total of 500,000 units of penicillin was given over a period of five days.

#### FATAL CASES

**Case 6.**—F L, a 54-year-old colored woman in coma, was admitted to the hospital on January 18, 1944. The day before she had had dull headache. The morning of admission she did not feel well enough to work and her husband later found her unconscious. There was nuchal rigidity and bilateral Kernig's sign. The spinal fluid was cloudy and showed 5,300 cells per cu mm, the majority of which were polymorphonuclear leukocytes and type VIII pneumococci. A continuous intravenous infusion of penicillin, 100,000 units daily, was started, but the patient died eight hours after admission, after only 40,000 units had been injected. This patient had pneumococcic meningitis complicated by diabetes mellitus and died without regaining consciousness.

**Case 7.**—C H, a white woman, aged 31, while under treatment for hyperthyroidism, complained of generalized malaise and mild frontal headache on February 8, 1944. Physical examination revealed nothing to account for her symptoms. When she vomited without preceding nausea, a spinal puncture was done. The spinal fluid was slightly cloudy, contained 175 cells per cu mm, and gram-negative intracellular diplococci, proved later to be meningococci. Shortly after this, small purpuric areas appeared over the whole body. Penicillin therapy was immediately begun by continuous intravenous infusion, each liter of physiologic saline solution containing 33,000 units of penicillin. The patient became stuporous, had convulsions, and died seven hours after penicillin was started. The blood culture was positive for meningococci. This patient had a fulminating meningococemia and meningitis complicating hyperthyroidism.

As in other bacterial infections, it seems that a certain proportion of patients with meningitis, especially those who have other diseases as well, or with fulminating infections, will fail to respond to any form of treatment.

#### Summary

Two patients with acute meningitis complicating other systemic disease died a few hours after penicillin therapy was begun. Five patients with

charged on February 16.

The dosage was 25,000 units intravenously during the first twelve hours and 4,200 units intramuscularly every two hours for 328,000 units, or a total of 352,800 units of penicillin in a period of nine days.

**Case 5 (*Meningococcic Meningitis*)**—A colored man, aged 37 years, was admitted to the hospital February 16, 1944, with severe headache, vertigo, sharp pains in his abdomen and lower back, and stiff-

it is important to give the patient more details pertaining to the preparation and quantity of these various food articles. It is also advisable for the physician to know the whys and wherefores for these various steps.

*Milk.*—Practically every patient with active ulcer is started on milk, a glassful, about 8 ounces, not a cupful (6 ounces), *every hour*, if he can possibly stand it, and usually he can—ordinary good milk, irrespective of its cream content. Sippy's advice to use certain percentages of cream and milk is too complicated and, from a practical standpoint, unnecessary. The hourly feedings should be kept up from the moment of arising to the moment of retiring, and a thermos bottle of milk should be kept at the bedside of the patient, so that a glassful may be taken if he awakens during the night. In this way, the patient consumes at least  $2\frac{1}{2}$  to 3 quarts of milk and, right from the start, obtains sufficient nutrition and a sufficient number of calories (1,500 to 2,000). The patients lose very little weight during their treatment.

The milk should not be taken ice cold; it may be room temperature or lukewarm, or hot if sipped. It should be taken alone—no crackers and no toast. If it should cause discomfort in some patients, owing to the formation of large curds, it should be modified by peptonization or the addition of lime water (a tablespoonful to the glass), or by the addition of sodium citrate (15 grains to the glass) or sodium bicarbonate (3 to 5 grains to a glass). All of these methods help to make the curds smaller. Naturally there is no objection if a patient wishes to add cream to his milk. It is unnecessary to drink any water because milk itself is 87 per cent water.

Occasionally one meets with patients who simply cannot take plain milk. They may be permitted to add a tablespoonful of a cereal coffee (like Postum) to a glass of milk or they may take buttermilk or any of the sour milk preparations. The patients are kept on a straight milk diet for two to three days. Some, who like milk, continue longer of their own accord because they find such a marked contrast to their previous state of misery and discomfort. If an individual is allergic to cow's milk, he may try goat's milk, or one may be forced to skip the milk period entirely.

*Eggs, Custards, Junkets, Gelatins.*—The eggs may be taken raw, shirred, very soft-boiled, or lightly scrambled with milk (not with butter, because the frying breaks up the butter into a fatty acid); if the patient absolutely dislikes eggs prepared in any of these ways, he may take them hard-boiled (for one half-hour or longer) and grated, and fresh butter may be added. Very little salt should be used. The intervals of feedings should still be one hour, but the patient may

alternate the eggs and the milk, or he may take the eggs and milk mixed together or separately at one feeding. There is no limit to the number of eggs that can be taken during twenty-four hours (6 to 8). If enough eggs are taken, a proportionate amount of milk may be eliminated. Raw egg white leaves the stomach very quickly and gives very little gastric stimulation. No omelette and no fried egg should be given. The poached, shirred, and soft-boiled eggs are found to be the most easily digested. In addition to the eggs, the patients are permitted custards, junkets, and gelatins. Junket is just another form of milk; custard is just another form of eggs; fruit gelatins give very little acidity, and leave the stomach rapidly—in one and a half to two hours. These foods, however, represent to the patient something solid, which is what they all ask for—something to bite into. The hourly feedings are kept up; milk may be taken alone or in smaller quantities together with the custard or jello, or the eggs may be taken alone or together with the custard or jello, etc. This routine is followed for three days. In fact, some have felt so well that that they have adhered to milk and eggs for longer periods of time. One patient who had a pyloric obstruction and who refused operation gained over 20 pounds in weight on milk and eggs combined with gastric lavage over a period of six weeks. The obstruction cleared up.

*Cereals.*—For the next three days, cooked and strained cereals are added: strained oatmeal gruel, cream of wheat, farina, arrowroot, strained hominy, pettjohn, strained barley gruel, or Pabulum; occasionally wheatena. This gives a wide variety. The oatmeal should be soaked overnight and boiled for several hours the next day and then strained, or cooked the night before and recooked the next morning. The cereals may be mixed with cream or milk, and seasoned with sugar, a little salt, and as much fresh butter as desired. A cereal may be taken twice a day, alone or added to the other foods to make a more substantial meal. For example: breakfast—cereal, eggs, and milk; lunch—eggs or custard, milk and jello; supper—cereal, eggs, and milk, but no toast, bread, or crackers. In between these meals, milk must be taken as nearly hourly as is possible, according to the comfort of the patient. Milk should be continued before retiring and during the night if the patient awakens.

*Cream Soups.*—The next addition is cream soups: cream of asparagus, cream of pea, cream of corn, cream of carrot, cream of mushroom, and occasionally cream of tomato, but not cream of spinach soup. Spinach is a strong secretagogue. The cream soups should not be made from meat stocks and should not be thickened with any, or only a very little flour. These cream soups con-

tain simply the essence of the vegetables in the form of a fine suspension mixed with milk and cream. For patients who do not have adequate cooking facilities at home, these soups may be easily prepared from dried vegetable flours or infants' puréed vegetables bought in cans, to which are added hot water or hot milk and cream. Oyster stew without the oysters may also be included in this group. Cream soups with their high fat content make an important addition to the diet. Thus a patient can now have a semblance of three main meals a day. For example: breakfast—cereal, eggs, and milk, lunch—eggs, cream soup, and milk, supper—cream soup or cereal, eggs, milk, jello or custard, etc. The milk feedings between meals must be continued.

**Potatoes, Etc.**—For the next three days are added potatoes, rice, noodles, spaghetti, macaroni. It is preferable to have the potatoes baked (and then mashed with a good deal of sweet butter) rather than boiled, because during the process of boiling they lose about 18 per cent of their mineral content and 8 to 16 per cent of their protein. One may permit baked sweet potatoes. The latter have higher caloric value, they contain more fat, starch, and minerals, but only half as much iron. A cream soup of potatoes becomes a relished addition. The noodles, spaghetti, or macaroni should be boiled and flavored with a plain butter or cream sauce, or a light mushroom sauce (without the mushrooms) or a little cream cheese or pot cheese, but no tomato sauce or highly seasoned cheese. The rice must be boiled for hours, until it is very soft, and then mixed with milk or cream, sugar, or very little cinnamon, may be added if desired.

**Bread.**—Most patients crave bread in some form and most patients suffering from hyperacidity eat a good deal of bread, but it is not a suitable food for them, and very frequently is the sole cause of their discomforts. This is particularly true of fresh bread, whether it be white, rye, whole wheat, or gluten. Bread is better tolerated if it is sliced very thin and then baked hard and dry in the oven—so-called melba toast, either white or dark. The harder the bread the more necessary are thorough mastication and pulverization, so that it may be more readily digested in the mouth. With each meal a patient may have several slices of melba toast with plenty of sweet butter or cream cheese. There are a number of such toasts on the market. As a substitute one may use dry crackers, crisp zwieback, pulled bread, Holland rusks, or Italian bread sticks.

**Cooked Vegetables.**—The next addition is cooked vegetables, puréed—finely mashed or strained—once a day.

Steamed vegetables are better than boiled be-

cause they do not lose so much of their mineral salts. Those allowed are a purée of peas, lima beans, squash, pumpkin, carrots, and string beans, those to be excluded are cabbage, broccoli, mushrooms, tomatoes, Brussels sprouts, corn, and spinach. Spinach, although it can be finely divided and creamed, increases gastric secretion and gastric acidity more than most vegetables. It is supposed to contain a hormone, secretin, which stimulates gastric secretion even when it is instilled into the duodenum.\*

With the addition of vegetables, the patient has a comparatively liberal selection of foods, so that he can remain on this diet for longer than three days. If the patient is sufficiently impressed with the importance of a thorough healing of the ulcer by this prolonged dietetic method, one is less liable to encounter much objection. He can now very readily take three main meals for example, breakfast—cereal, toast and butter, eggs and milk, lunch—cream soup, potato, green vegetable or eggs, and milk, supper—cereal, noodles or rice, eggs or cream soup, custard, junket or jello, and milk. Milk must be continued between meals and before retiring, even when patients are on a full diet.

**Fish.**—The next addition is lean and tender fish, boiled or broiled, seasoned with a little lemon juice and butter melted on the hot plate or on the hot fish. Drawn butter, cooked over a high flame, is not advisable, as the high heat breaks up the butter into a fatty acid, while melting the butter more gently on a hot dish does not. Fish of the lean type are halibut, cod, scrod, sole, pike, pickerel, perch, flounder, striped bass, brook trout, and red snapper. The fat types of fish, to be avoided, are bluefish, whitefish, salmon, mackerel, sardines, shad, eel, pompano.

For those patients who like fish, this addition provides a diet which makes it simple for the management of the general household and of ample variety to satisfy the patient for a longer period of time. At first, the fish should be given only every other day, to see how it is tolerated.

**Poultry and Meats.**—One generally starts with the white part of chicken, either boiled or broiled or hashed. This is a short-fibered lean meat, whereas beef is long-fibered. At first the chicken should be given every other day, alternately with the fish.

Next, one may add finely chopped or scraped lean beef, either grilled or raw, but not fried. Later on, a tender lamb chop, a little roast lamb, and sliced boiled ham may be included in the menu.

Fish and meats are true intragastric stimulants, they require a long period of digestion, which necessitates a large amount of gastric work, and they stimulate a high acid output,

these disadvantages are somewhat counterbalanced by the fact that they absorb a comparatively larger amount of acids. The more fat in the fish or meat, the longer the emptying time of the stomach, which in turn means a longer period of motor and secretory activity. The lean fish are digested more easily than the meats. Small portions are more readily taken care of.

*Desserts.*—With the addition of meats the patients are on a full diet, with the exception of desserts. These can now be added in the form of finely puréed applesauce (made from sweet eating apples) or a purée of cooked sweet peaches or eating pears; no berries; no rhubarb.

The patients frequently have a hankering for sweets. Almost fifty years ago, Strauss<sup>10</sup> found that sugar solutions reduce gastric secretion. Sweet desserts have therefore frequently been recommended as permissible in cases of hyperacidity, but if gastric atony is associated with hyperacidity, the sugars undergo fermentation and increase the already existing heartburn or flatulence. Honey is frequently well tolerated. Pastries, heavy pies, rich cakes, and mixed puddings are forbidden. In addition to the custards, junkets (either plain or chocolate), and fruit gelatins, given very early in the diet, later on may be added blancmange, light soufflés (vanilla, lemon, or less frequently chocolate), corn starch pudding, rice pudding, and also plain dry cookies, plain sponge cake, or lady fingers. Candies depress secretion and delay evacuation in proportion to their sugar content and the amount of candy ingested. They are greatly influenced by the flavoring substances and added ingredients, such as milk, eggs, or chocolate. Chocolate candy seems to give higher acid figures than the plain sugar candies. Simple gumdrops leave the stomach rapidly, with little acid production. This list gives the patients a variety of desserts which always makes them more content.

Very often I have found that patients' complaints about restrictions in their diet were due to the indefinite way in which the physician recommended the regimen; and this occurred because the physicians themselves were not convinced. It is to overcome this uncertainty that I have worked out the above regimen in such detail. As it stands, it is the diet I advise for cases with discomfort from hyperacidity. The ulcer patients must follow it strictly for at least six months to a year or longer. However, during this time, when the patients will be doing well, they will ask for additions to their diet, and the physician must be prepared to answer many questions and give more liberties now and then. In order to do this wisely, the following knowledge concerning the other food elements will be of great aid.

*Raw Fruits and Fruit Juices.*—On account of their roughage and their tendency to stimulate gastric secretion, these foods are generally eliminated for a long time. Overindulgence in fruit juices, pure or diluted, is one of the frequent causes for distress in patients with hyperacidity. Very often we observe attacks of hyperacidity after fresh fruits have come into season. There is a wide individual variation in tolerating the different organic acids. More people get discomfort from orange juice than from grapefruit. The layman has been brought up with the faulty impression that orange juice is an efficient alkalinizer.

He does not realize that this applies to its effect upon the general system rather than its direct action in the stomach. Here it evokes a high acidity for an hour.<sup>11</sup> From the standpoint of the vitamin C requirement, it may be wise to let the patient have about 4 to 6 ounces of fruit juice daily, after he has reached a full diet for several weeks, or it may have to be given at any time if he shows any signs of vitamin C deficiency. This occurs very rarely, however. Experience should induce people to avoid whatever fruit that they have found is likely to provoke distress. They may tolerate, in small amounts, very ripe, almost dark bananas, very ripe, soft peaches, persimmons, sweet California grapes, and hothouse grapes. Occasionally patients may be permitted to chew the various fruits in order to get the juice if they do not swallow the pulp of the fruits (cantaloupe, watermelon, and other melons) No berries.

*Raw Vegetables.*—What has been said about raw fruits applies equally to raw vegetables—namely, that their roughage makes them inadvisable. Thus salads, celery, cucumbers, olives, pickles, cabbage, etc., are prohibited. Large quantities of vegetable juices are also not advisable because of their secretagogue effect. The present indiscriminate wave of enthusiasm favoring the use of raw vegetables or vegetable juices is exaggerated in importance; but one may add about 4 to 6 ounces of tomato juice daily when the patient has fared well with his diet.

*Cooked Vegetables.*—To those vegetables already permitted may be added asparagus tips and puréed beets, the tops of young cauliflower, artichoke bodies, oyster plant, and, rarely, tomatoes.

*Shellfish.*—The difficulty with shellfish, from the gastric standpoint, is their coarseness rather than their secretagogue action. One may permit an oyster or clam stew, not highly seasoned, but only the very soft part of the oyster or clam should be taken. Once in a great while one may allow an especially tender and finely divided broiled lobster or a soufflé of lobster; otherwise

the fibers are too coarse. *Caviar*, if not too salty, is permitted.

*Meats, Poultry, and Game*—As has been said, the basic diet for hyperacidity includes chicken scraped or chopped meat, thinly sliced boiled ham, lamb chops, roast lamb, white meat of turkey, quail, pheasant, and, rarely, soft veal. After a patient has done well for three or four months he may be permitted a thin slice of very tender roast beef. Whether it is rare, medium or well done makes no difference as far as the emptying time or wave of acid secretion is concerned. Beefsteaks are only rarely tender enough. Pork is difficult to digest because of the fat surrounding the meat fibers. A soft sweetbread, broiled or en *casseroles*, or sheep's brains may be permitted, if prepared without grease or frying. Veal is allowed only if very tender. Occasionally a small portion of calf or chicken livers, broiled may be taken without difficulty. Kidneys are too hard and tough. Goose duck, tongue and spiced meats are on the forbidden list.

*Soups*—Only the cream soups mentioned before are allowed, no plain bouillions, broths, or beef extracts, as they are highly secretagogue. Occasionally a jelled consommé.

*Cheese*—The highly seasoned or spiced varieties, such as *cammembert*, should be omitted.

*Nuts*—Nuts are rough and irritating to the mucous membrane, but almonds are an excellent antacid. I have often advised a combination of finely ground sweet almonds (nine parts) and finely ground bitter almonds (one part) in half-teaspoonful doses for relieving the sensation of heartburn, instead of bicarbonate of soda.

*Beverages*—Milk is without doubt the ideal drink. It cannot be advised too often that even when ulcer patients are on their so called full diet, milk of some kind, plain or malted, should be taken once or twice between meals and before retiring. If at all feasible, coffee should be strictly forbidden at all times. It is a strong gastric stimulant, irrespective of whether it is free of caffeine or not, because it is the oil extractives and the flavoring agents which cause the secretion. Weak tea is decidedly less stimulating than coffee but should be prepared fresh and not strong. Cocoa, although more stimulating than tea, is better than coffee and may be used as a change, particularly a bitter cocoa, if prepared weak with water and with milk. Some patients get a feeling of fullness after cocoa, and this is probably due to an excessive amount of secretion which the cocoa may cause. Any of the cereal substitutes for coffee, such as Postum, is all right. Many people like to finish their meals with a warm drink. A little hot water, a weak infusion of breakfast tea or camomile tea or peppermint tea may be taken.

It has been shown that peppermint actually hastens the emptying time of the stomach.<sup>11</sup>

### Bad Habits in Eating and Drinking

There are certain bad habits of eating and drinking that the patients must be warned against.

*Do not drink water with meals*. I consider this one of the most important rules to be observed in cases of hyperacidity. In fact, any liquid with a full meal is inadvisable, especially if a soup has been included. It is best to take the meals dry. If no soup has been consumed, a glass of milk is permissible. Plain water is a strong gastric stimulant. I have seen 50 cc of water stimulate 250 cc of gastric juice of high acidity and high peptic activity. I have employed plain water as a test meal instead of the Ewald breakfast and found it just as efficient.<sup>12</sup> Iced water is particularly harmful, and the American habit of drinking glassful after glassful of iced water with meals is to be absolutely condemned. I have noted many a case of digestive difficulty clear up entirely when this unfortunate custom is stopped. It takes about twenty minutes for a glass of ice water, when drunk, to become the normal temperature of the body, during this time there undoubtedly is a delay in the digestion, large amounts of iced water bring about a correspondingly longer delay. Furthermore, the rapid transit of iced water into the upper small bowel can have a deleterious effect upon the biliary tract, liver and pancreas. For similar reasons, ice cream or ices, especially if eaten rapidly, are not the logical dessert after a big meal. They are less harmful if taken occasionally in small portions and eaten very slowly, between meals, instead of the milk. The taking of water or liquids with meals is particularly contraindicated in those cases in which the secretory disorder is combined with motor inefficiency. With undisturbed motor activity, a moderate amount of fluid taken with or at the end of a meal may help to dilute the acid secretion and may be permitted to those who are particularly habituated. For this purpose I prefer one of the natural or artificial alkaline waters. If they are highly carbonated, it is wise to stir out the gas before drinking them.

Finally, there are other dietary principles that should be observed—namely, to avoid rich foods, tough foods and fried foods, to avoid seasoning of foods with an excess of salts, spices, or condiments, to eat slowly and masticate thoroughly, not to eat heavily when physically tired or emotionally upset.

### Discussion

I realize fully that critics of such a fixed regimen for ulcer patients may consider it impractical to have the same routine of diet for every patient.

# MINIMAL CHEMOTHERAPY IN PNEUMONIA

## Preliminary Report of a Two-Dose Ten-Gram Method Using Sulfathiazole and Sulfadiazine

LUIGI P. MINETTO, M.D., New York City

THE present communication is a report of an investigation of 30 cases of acute pneumonia treated with sulfathiazole and sulfadiazine which totaled only 10 Gm. in each case. The results were eminently satisfactory in the great majority of instances, with a rapid fall in temperature to normal, prompt clearing of the pulmonary lesion roentgenologically, and complete absence of toxic manifestations. These cases are presented in the hope that future work by other investigators may give sufficient data to allow the merits or disadvantages of the method to be better evaluated.

The diagnosis of pneumonia was determined by clinical history, physical examination, roentgenogram, and sputum typing. The method of treatment consisted of the oral administration of an initial dose of 2 Gm. of sulfadiazine and 3 Gm. of sulfathiazole, followed six hours later by a second dose of 5 Gm. of sulfadiazine. Equal parts of sodium bicarbonate were administered with each dose.<sup>1</sup> Sulfathiazole was used in conjunction with sulfadiazine with the initial dose,

because it is rapidly and evenly absorbed from the gastrointestinal tract, absorption being complete within three to six hours.<sup>2</sup> Sulfadiazine, which is less rapidly absorbed and more slowly excreted, was used to maintain a more evenly prolonged blood level.<sup>3,4</sup> Supportive therapy was stressed. At least 2,000 cc. of fluids were given daily, along with sodium chloride to facilitate its administration.<sup>1</sup> Barbiturates were administered to relieve restlessness. Intranasal oxygen was given when indicated.

On admission sputum typing, blood culture, blood count, urine analysis, and roentgenogram were obtained. Another blood count was performed twenty-four hours later. Urine analyses were performed for three consecutive days. The roentgenogram was repeated six days after admission. Sulfadiazine blood levels were taken the morning after admission and twenty-four hours later.

Complete success with excellent results was obtained in 25 cases (see Table 1). Critical drop of the temperature to normal by crisis occurred in 24 patients within forty-eight hours. In one patient the temperature became normal by lysis in sixty hours. The roentgenographic clearing

Formerly Resident Physician, the Second Medical Division, Service of Dr. B. F. Donaldson, City Hospital, Welfare Island, Department of Hospitals, New York City.

FIG 1 Case 3 Roentgenograms of chest A—Taken day of admission B—Taken five days later

of the consolidating process was marked in 21 patients and moderate in four. A typical temperature curve and roentgenographic clearing is shown in Chart 1 and Fig 1.

A slight secondary temperature rise was noted in 6 of the 25 cases. Progression of symptoms or lesions was not encountered. General clinical improvement was excellent after the initial critical temperature drop. Five of the cases showed the same degree of marked roentgenographic clearing of pulmonary lesion as those cases that did not have a secondary temperature rise. Moderate roentgenographic clearing was present in one case. This type of temperature curve is demonstrated in Chart 2.

### Case Reports

Two cases were partial failures.

**Case 10**—A 56-year-old white bartender showed massive involvement of four lobes with marked dyspnea, cyanosis, and delirium tremens. Two doses produced only moderate improvement. Temperature declined gradually from 104 to 102 F within sixty hours. Seventy-two hours after the second dose, a third dose of 5 Gm. of sulfadiazine was administered. The temperature dropped to normal eight hours later. There was no secondary temperature rise and the patient continued to improve clinically. The roentgenogram showed moderate clearing in fourteen days.

**Case 19**—A 21-year-old male Puerto Rican defense worker was admitted in an extremely toxic condition. There was only moderate clinical improvement, and forty-four hours after the second dose of sulfadiazine a third 5 Gm. dose was administered. The temperature dropped to normal by crisis within sixteen hours, without any secondary rise. The roentgenographic clearing was as marked in seven days as those cases that were completely successful. This case is illustrated in Chart 3.

Three cases were completely unsuccessful and the standard method of sulfadiazine therapy had to be instituted.<sup>6, 8</sup>

**Case 8**—A 40-year-old Puerto Rican housewife with a 4 plus serology was admitted, acutely ill. Clinical response was fair to two doses of chemotherapy. A third 5 Gm. dose was administered thirty-one hours after the second dose proved to be ineffectual, and the temperature remained elevated, fluctuating between 102 and 104 F. One Gm. of sulfadiazine every four hours was started eight hours later, with slow but definite improvement. The temperature dropped by lysis to normal on the seventh hospital day. Roentgenographic clearing was moderate after seven days.

**Case 12**—A twenty-year-old Negress with a 4 plus serology did not improve clinically with the two doses, or with a third dose of 5 Gm. of sulfadiazine administered thirty hours later. Ten hours after the third dose, 1 Gm. of sulfadiazine was given every four hours. Her temperature fell by lysis

CHART 1

CHART 2

from 105 F. to normal on the seventh hospital day. Roentgenographic clearing was moderate after seven days. A complicating factor in this case was vaginal bleeding for ten days which necessitated a 500 cc. transfusion.

**Case 13.**—A 44-year Negress did not show progressive clinical improvement after a third 5 Gm. dose of sulfadiazine was administered forty hours after the second dose. Eight hours later 1 Gm. of sulfadiazine was given every four hours for five doses, with marked clinical improvement. Her temperature became normal on the fifth hospital day. Roentgenographic clearing was marked after eight days. This case is illustrated in Chart 4.

Positive sputum typing was obtained on 15 patients. The pneumococci typings were distributed as follows: One case each of Types I, VI, XII, XIII, XVII, XIX, XXIII, and XXXI; two cases each of Types V and VII; and three cases of Type III. Blood cultures were sterile. The leukocyte count averaged 20,000, and ranged from 9,000 to 34,000. Blood counts taken twenty-four hours later were not remarkable. Urine analyses performed for three days did not show any abnormalities.

Roentgenograms of the chest were repeated within an average of six days after admission; the interval ranged from three to fourteen days. The clearing was considered marked when there was a faint trace of, or no evidence of the consolidating process as compared with the admission film. In reviewing cases of pneumococcal pneumonia treated by the standard method of sulfadiazine dosage and comparing the results with the two-dose method, it was noted that the roentgenographic clearing was more prompt and complete in the latter in a great majority of instances.

Sulfadiazine blood levels were obtained the morning after admission and twenty-four hours later. The initial sulfadiazine blood levels were taken within an average of twelve hours after the first dose had been administered, and the time of taking these levels ranged from two to twenty hours. The blood levels averaged 8 mg. per 100 cc. of blood in twelve hours, and then gradually declined to 5 mg. per 100 cc. of blood in twenty-four hours, and varied from 1 to 2 mg. per 100 cc. of blood in forty-eight hours. Past experience has failed to show any correlation between the therapeutic effectiveness of the drug and the concentration of free drug in the blood. Many of the blood levels during the therapeutic phase were below the 5 mg. per 100 cc. of blood considered as the proper level for therapeutic effectiveness.<sup>9</sup>

There were no toxic reactions in any of the 30 cases. Nausea, vomiting, crystaluria, hematuria, anuria, skin rash, drug fever, agranulocytosis, and hemolytic anemia were entirely absent.<sup>10</sup> The lowest dosage of sulfadiazine reported in the literature as the cause of a toxic reaction was 11 Gm.<sup>11</sup> In this instance the patient had received 11 Gm. of sulfadiazine, which led to anuria. The possibility of sensitization by a previous course of sulfathiazole treatment was present in this case.

No complications were noted.

### Summary and Conclusion

Thirty consecutive cases of acute pneumonia were treated orally with an initial dose of 2 Gm. of sulfadiazine and 3 Gm. of sulfathiazole, fol-

### CHART 3

#### CHART 4

lowed six hours later by a second dose of 5 Gm of sulfadiazine. Twenty five cases were completely successful, with excellent clinical and temperature response. Marked roentgenographic clearing of the consolidating process was noted in 21 cases within an average of six days after admission. Two cases were partial failures and necessitated a third dose of 5 Gm of sulfadiazine, with excellent results. Three cases were completely unsuccessful and the standard method of sulfadiazine therapy had to be instituted. Toxic reactions or complications were not encountered.

## HORACE WELLS CENTENARY CELEBRATION

This year marks the one hundredth anniversary of the discovery by Horace Wells, a Hartford dentist, of the anesthetic effects resulting from the inhalation of nitrous oxide. Because of the significance of Wells' great contribution to dental and medical science the American Dental Association is planning a centenary celebration which will serve to honor Horace Wells and also acquaint the profession and the public of the important part he played in the discovery of anesthesia. The main celebra-

tion will be held in Hartford on December 11, 1944, the centenary anniversary date of the discov-

Connecticut State Medical Society to share in this celebration and the Council has appointed Dr H G Jarvis, Dr J H Howard, and Dr Barker as the representatives of the Society to serve on the general committee—*Connecticut State M J, July, 1944*

moved with sponge forceps, some foul-smelling placental tissue came with them. Uterus and vagina were packed after the uterus had been wiped with a sponge, and a transfusion was given. Blood pressure the next day was 155/90. The packing was then removed, without recurrence of bleeding.

The patient ran a low-grade fever, with foul lochia, until April 19, 1913, the seventeenth day post-partum, when she had another vaginal hemorrhage. The uterus and vagina were again packed and another transfusion was given. The packing was removed in forty-eight hours. From then on she made an uneventful recovery and was discharged on April 28, with a blood pressure of 120/80.

In the follow-up Toxemia Clinic on June 21, 1913, her blood pressure was 120/80; her urine was normal; her urea clearance was 81 per cent. On November 30, 1913, her blood pressure was 130/80, urine was normal; there was no edema; the abdomen was soft; the uterus was well involuted; the cervix was slightly eroded.

*Final Diagnosis.*—Severe pre-eclampsia with normal blood findings, hypertensive disease complicating pregnancy, twin pregnancy, version and breech extraction, shock, paralytic ileus, post-partum hemorrhage

Bronx, New York

MEDICAL PROFESSION IS WORLD'S GREATEST FRATERNITY

The medical profession is the world's greatest fraternity, said Walter B. Cannon, M.D., president

of the American Medical Association, when he addressed the society, he is welcomed by his fellow doctors. In-

our professional interests and the community of our efforts. As a disease itself is no respecter of national or racial differences, so the doctors in their humane service do not respect them. Even in bitter warfare among civilized peoples, wounded enemy captives receive scrupulous surgical care. Though methods of treating injury and disease may differ in different lands, the aim is every where the same—

between nations are recognized. The world-wide uniformities of the phenomena of infections, malnutrition, traumatism, and healing render such barriers absurd. Investigators of these phenomena in various countries publish openly their methods of

recent times have been an awareness that medical

curing them, and a readiness to utilize progressive measures in practical application. While procedures which have been proved good by past experience are respected, new procedures resulting from scientific discoveries are considerably tested for their greater or their novel utility. In short, the medical profession is not tightly bound in tradition, but is free and forward-looking. Steps of unpressive advance have compelled the profession to abandon notions of rigidly fixed patterns of practice, and instead to expect the disclosure of better ways of solving the

urgent problems presented by mankind, disabled, in misery, and faced with premature death. Solutions of these problems may be found in any nation. Because they are urgent and insistent problems, incidental barriers of prejudice or of exclusive nationalism represent folly instead of wisdom.

"Unfortunately there is a difficult natural barrier which, despite the freedom of exchange of medical knowledge, despite the generous fraternity of the medical profession, despite the readiness of the profession to accept and use effective new discoveries, may block the ways which could lead to mutual advantages. This barrier, a marked difference of language, exists between the Soviet Union and the United States. Though many leaders of Soviet medicine can read English medical literature, relatively few are familiar with the Russian medical publications of the English-speaking nations, and little is known of progress in surgery, defect, ing issue

papers from the Russian, survey articles written by American experts on various aspects of Soviet medicine, news of current medical events in the U.S.S.R., reviews of Soviet medical books, and abstracts from Soviet medical periodicals. At a time when the Soviet Union is enduring magnificently and most valiantly the exacting strain of total war, and when exigencies of mobile unique situations, the war medicine.

posses of the society plan Soviet Union to establish an exchange of students and teachers

ship of physicians in the two countries and thereby will help to promote mutual acquaintance and to lessen ignorance and misjudgment among the citizens of two great and powerful nations.—Editorial in J. Med. A. of Georgia, June, 1914

# Postgraduate Medical Education

*Programs arranged by the Council Committee on Public Health and Education of the Medical Society of the State of New York are published in this section of the JOURNAL. The members of the committee are Oliver W. H. Mitchell, M.D., Chairman (428 Greenwood Place, Syracuse); George Baehr, M.D., and Charles D. Post, M.D.*

## Four Teaching Days on Poliomyelitis

FOUR teaching days on poliomyelitis were held at the end of August. The first was held at Homer Folks Tuberculosis Hospital in Oneonta on August 23. The program opened at 4:00 p.m.; the meeting was called to order by Dr. Le Roy S. House, president of the Otsego County Medical Society. The chairman of the meeting was Dr. Marjorie F. Murray, regional chairman in pediatrics. The first lecture was "Epidemiology of Poliomyelitis," delivered by Dr. James E. Perkins, Director, Division of Communicable Diseases, State Department of Health, Albany. This was followed by "Clinical Features—Pathology, Diagnosis, and General Treatment," by Dr. James L. Wilson, professor of pediatrics and director of the department of pediatrics, New York University College of Medicine. The program concluded with "Physical Therapy in the Acute and Convalescent Stages," by Dr. Philip M. Stimson, associate professor of clinical pediatrics at Cornell University Medical College. The meeting was under the auspices of the Broome, Chenango, Delaware, Otsego, Sullivan, and Tioga County Medical Societies, the Medical Society of the State of New York, and the New York State Department of Health.

The same program was repeated at a teaching day at Vassar Brothers Hospital in Poughkeepsie on August 30. The meeting was called to order at 8:00 p.m. by Dr. Harry A. LaBurt, president of the Dutchess County Medical Society. The chairman of the meeting was Dr. Donald R. Reed, acting regional chairman in pediatrics. This program was presented by the Dutchess, Orange, Putnam, Rockland, and Westchester County Medical Societies, the Medical Society of the State of New York, and the New York State Department of Health.

A poliomyelitis teaching day was held in the Academy of Medicine in Rochester on the afternoon of August 31.

Dr. Benedict J. Duffy, president of the Medical Society of the County of Monroe, called the meeting to order at 3:00 p.m.; the chairman of the meeting was Dr. Albert D. Kaiser, regional chairman in pediatrics. Dr. Perkins spoke on "Epidemiology of Poliomyelitis." Dr. Douglas P. Arnold, chief of the pediatric service of Buffalo General Hospital, followed with "Clinical Features—Pathology, Diagnosis, and General Treatment." The lecture, "Orthopaedic Measures," by Dr. John C. McCauley, Jr., associate professor of clinical orthopaedic surgery, New York University College of Medicine, closed the program. The teaching day was under the auspices of the Livingston, Monroe, Ontario, Orleans, Seneca, Wayne, and Yates County Medical Societies, the Medical Society of the State of New York, and the New York State Department of Health.

A meeting of the Nassau County Medical Society, at 9:00 p.m. on August 18, at the Meadowbrook Hospital, Hempstead, was given over to postgraduate instruction in poliomyelitis.

The speakers were Dr. James E. Perkins, who discussed epidemiology of poliomyelitis, and Dr. John F. Landon, instructor in pediatrics, Willard Parker Hospital, College of Physicians and Surgeons, Columbia University, who spoke on "Diagnosis and General Treatment of Poliomyelitis."

The program was presented as a cooperative endeavor between the Council Committee on Public Health and Education of the Medical Society of the State of New York and the New York State Department of Health.

## "Penicillin Therapy"

POSTGRADUATE instruction in penicillin therapy was arranged for the Delaware County Medical Society for September 12 at 6:30 p.m. at the Hamden Inn in Hamden. Dr. Paul C. Clark, assistant professor of clinical medicine at

Syracuse University College of Medicine, was the speaker.

This instruction was presented as a cooperative endeavor of the Medical Society of the State of New York and the State Department of Health.

## COMPULSORY PREMARITAL PHYSICAL EXAMINATIONS FOR TUBERCULOSIS

No states require a premarital physical examination for tuberculosis, according to the *Bulletin* of the National Tuberculosis Association. Three states, Washington, North Carolina, and North Dakota, have legislation which prevents persons from marrying who have infectious tuberculosis, and three other states, Delaware, Indiana, and

Pennsylvania, have general laws covering the marriage of persons with a transmissible disease.

Tuberculosis is not specified in these laws, it was stated, but would be covered by the term "transmissible."—*Bull. Federation of State Medical Boards of the United States*

## Hospital Charges for X-Ray, Pathology, Anesthesia, and Physical Therapy

*Following the publication in the September 1, 1944, issue of the JOURNAL of a memorandum on this subject recently submitted to the authorities by the Joint Council of Pathologists, Radiologists, Anesthesiologists, and Physical Therapy Physicians, the JOURNAL here presents for the information of its readers material which went to the authorities from the Bureau of Workmen's Compensation of the Medical Society of the State of New York.*

*In brief, all of this is to show that hospitals may not render medical care; and, second, that hospital functions are circumscribed both under the Corporation Laws and the Workmen's Compensation Law of New York State.*

*A critique of the Court of Appeals' decision in the Sausser case, defining "Roentgenology" as not being of the practice of medicine, will be subsequently published.—Editor*

June 12, 1944

To the Honorable Orrin Judd, Solicitor General  
Capitol  
Albany, New York

I am enclosing, as per my promise, a memorandum which we wrote back in 1937 concerning the rights of hospitals to charge for services rendered by physicians on their staffs. I believe the argument is even more valid today in view of the specific amendments to the *Workmen's Compensation Law*, operative June 1, 1944, which were discussed at the meeting last week before Commissioner Corsi of the Labor Department, which you attended.

May I further call your attention to Section 13-c(2), effective June 1, 1944, which states:

"No claim for services in connection with x-ray examination, diagnosis, and treatment of any claim shall be valid or enforceable except by a physician duly authorized as a roentgenologist by the Industrial Commissioner for services performed by such physician or under his immediate supervision."

May I further call your attention to Section 13-d of the *Workmen's Compensation Law*, which, after defining the reasons for the removal of a physician from the panel of physicians authorized to treat compensation claimants, specifically, in paragraph (g), exempts the x-ray specialist from the penalty provided for rebating or fee-splitting by the following statement:

"Except reasonable payment not exceeding 33 1/3 per cent of any fee received under this chapter for x-ray examination, diagnosis, or treatment may be made by a physician duly authorized as a roentgenologist to any hospital furnishing facilities for such examination, diagnosis, or treatment."

Section 13-f, as amended in 1935, was not disturbed by the recent amendments. This section states:

"Fees for medical services shall be payable only to a physician or other lawfully qualified person permitted by Section 13-b of this chapter to render medical care under this chapter or to the agent or to the executor or administrator of the estate of such physician. . . . Hospitals shall not be entitled to receive the remuneration paid to

physicians on their staff for medical and surgical services."

Section 13-b(3) provides that laboratories and bureaus engaged in x-ray diagnosis or treatment, etc., which participated in the diagnosis or treatment of injured workmen under this chapter, shall be operated or supervised by *qualified physicians* duly authorized under this chapter and shall be subject to the provisions of 13-c of this chapter. Section 13-c refers to the licensing of such laboratories and bureaus.

Rule No. 17 of the Rules and Regulations promulgated by the Industrial Commissioner covering Chapters 258 and 930 of the laws of 1935 amending the *Workmen's Compensation Law* provides:

"Hospitals and Dispensaries shall not operate a medical bureau or clinic for the purpose of rendering medical care and treatment to compensation cases. . . . Hospitals and dispensaries shall not render medical care and treatment to ambulatory compensation cases except for the emergency treatment."

All this to show that the hospitals may not render medical care and that their functions are circumscribed both under the corporation laws and the *Workmen's Compensation Law* of this State.

May I draw your attention to a decision by Mr. Justice McLaughlin, which was published in the *New York Law Journal* on Saturday, June 13, 1936, in the case of *Posner v. Israel*. These two physicians had formed a partnership to engage in the solicitation business and dividing the fees at a time when it was not illegal to carry on these practices although it was unethical. Their activities were confined to workmen's compensation cases. On July 1, 1935, the *Workmen's Compensation Law* was amended, forbidding splitting any fees received for treating injured employees. Justice McLaughlin held that since that law went into effect (July 1, 1935) the partnership became illegal. The prayer of the plaintiff to dissolve it on that ground was granted. An interlocutory judgment of dissolution was granted.

If in accordance with the terms of the amended *Workmen's Compensation Law*, a physician has entered into a contract with a hospital to provide x-ray services on a full-time salary basis, and if after June 1, 1944, such contract includes the acceptance of a salary and the turning over of all fees for x-ray

[Continued on page 2036]

[Continued from page 2034]

examinations made to the hospital, it would seem that such contract is null and void and contrary to the purpose of the amended *Workmen's Compensation Law*\* as defined in the various sections mentioned above.

DAVID J. KALISKI, M.D., *Director*

February 5, 1937

To the Industrial Commissioner:

You have very kindly referred to me a brief submitted by the voluntary hospitals of the City of New York to the Attorney General protesting against your construction of Section 13-f of the amended *Workmen's Compensation Law*.

It is the contention of the voluntary hospitals of the City of New York that Rule 22 promulgated by the Industrial Commissioner is an erroneous construction of the language of Section 13-f of Chapter 258 and

"that it has the effect of depriving the hospitals of their legal right to charge for special services in compensation cases, as they do in all other types of cases, except where indigent patients are involved, and that the rule in question will cause them substantial damage."

Section 13-f states—

"Fees for medical services shall be payable only to a physician or other lawfully qualified person permitted by Section 13-b of this chapter to render medical care under this chapter. . . . Hospitals shall not be entitled to receive the remuneration paid to physicians on their staff for medical and surgical services."

The hospitals contend that "the proper, as well as the literal, construction of this provision excludes all services other than *medical and surgical*." Roentgenology is an integral part of medicine and surgery and in its fullest and completest sense means a special service rendered by an especially qualified physician. As in other branches of medicine, certain phases of this work may be rendered by trained technicians, just as in medicine and surgery nursing and other technical or nonmedical help is often essential, but, actually, x-ray service is a part of medical service and not a special service in the sense that it can be provided by the hospital without the intervention of a properly qualified physician. The same is true of other laboratory services, especially pathology, anesthesia, and physiotherapy. All of these require special training on the part of a physician and in the strict sense of the word are a part of medical service. These services are available in a hospital, but are at the command of the physicians of the hospital, who are the only persons qualified and licensed to utilize them. A roentgenologist is personally responsible (legally) for his acts and is himself liable rather than the institution by which he is employed.

The hospitals maintain that this special service is impersonal and does not involve a direct relationship of doctor and patient. This is not a valid argument and is indeed not a fact. In order that an injured claimant may be properly cared for, it is necessary in many instances that the roentgenologist establish

a direct relationship with the patient and his attending physician and perhaps review the records of the case in order to arrive at a correct diagnosis and when necessary render the proper treatment, if treatment by radiation therapy is required. It is often necessary for the x-ray specialist to testify as to the facts in the case before the referee. He must testify as a licensed physician especially qualified in x-ray diagnosis and/or treatment. That the hospitals have relegated to themselves the right to utilize x-ray and laboratory service as a means of revenue to the hospital in no sense disturbs the argument that it is a medical service and not comparable to the ordinary hospital care.

It was not the intention of the framers of the amended *Workmen's Compensation Act* to permit the hospitals by direction or indirection to practice medicine. It was clearly intended that only a licensed physician should be permitted to practice medicine; and a licensed physician on the duly constituted staff of a voluntary hospital was exempted from certain provisions of the *Workmen's Compensation Act* in respect to registration in order to make it possible for him to render service to injured workmen who might be hospitalized because of the severity of their injuries.

That hospitals should not be entitled to receive remuneration paid or payable to physicians for medical and surgical service was clearly indicated in Section 13-f of Chapter 258. The argument that city hospitals are entitled to recover from an employer for medical service does not support the contention of the hospitals that a hospital may render such medical and surgical service *per se*. It is only because of certain restrictive and prohibitory clauses in the New York City Charter that hospitals have assumed the right to collect for services rendered by physicians and for which only physicians should be compensated. It may be pointed out here that these prohibitory clauses have been removed from the new Charter of the City of New York specifically for workmen's compensation cases. It is also contemplated that the Municipal Assembly will take steps to pass legislation to remove this prohibition against a physician in the city hospitals being compensated so that physicians may be paid during the period between now and January 1, 1938, when the new Charter goes into effect. This is an irrefutable argument, in which the municipal hospitals agree that hospitals are not entitled to payment for medical services. The purpose of restricting municipal hospitals to emergency care only was not with the idea of overcoming the prohibition against the payment of physicians, but a realization of the fact that workmen's compensation claimants are not public charges and should be treated as semi-private or private patients in accordance with their social and economic status.

In their argument the voluntary hospitals state that prior to the amendment of the *Workmen's Compensation Law* in 1935, "Regulations of the care of injured employees in and outside of hospitals had fallen into a state of confusion and various undesirable practices had resulted. There was need of precise and remedial provisions." This argument is valid. It was necessary that the injured claimant should be able to call upon those who had participated in the diagnosis and treatment of his injuries for medical testimony in establishing his claim before the Department of Labor. It was obvious that competent testimony was necessary and only a duly qualified physician, either in

\* Section 1264 of the *Education Law* similarly amended, effective April 4, 1944.

# RELIEF *mist*

● Few patients are more immediately grateful to their physician than the acutely wheezing asthmatic. To transform strangling dyspnoea into easy normal breathing is one of the most dramatic, deeply appreciated acts of medicine.

With 'Wellcome' Solution of Epinephrine Hydrochloride 1:100, a few quick squeezes of the nebulizer bulb produces a mist which when inhaled orally quickly reaches those portions of the bronchial tree and mucosa where action is most needed. Nervousness and tachycardia, which often follow hypodermic epinephrine, are usually absent after local use.

[Continued from page 2036]

the hospital or outside the hospital, could render proper testimony. The hospital as an impersonal being is in no position to act in this capacity; therefore legislation was necessary to restrict the scope of activity of the hospital to bed and board care, and to provide for the attending medical staff those adjuvant services that are necessary in the care of the sick and injured. They are a part of the physician's armamentarium; among them x-ray service may be mentioned. The hospital provides the apparatus, certain technical help, and other services. But in the last analysis the physician controls and animates the services and renders the diagnostic and therapeutic help. It is he who is to be compensated for the service rendered. The fact that the physician is hired on a salary basis in no wise alters the validity of this argument. In some instances he renders the service gratis, as do other physicians and surgeons connected with the institution. In some instances he is paid an honorarium, and in others a salary, either for full- or part-time services. That adequate arrangements are possible to remunerate and reimburse the hospital for its overhead in supplying the roentgenologist with apparatus, material, and technical service goes without saying. This is entirely feasible and a means has been suggested for bringing it about.

Rule 22, to which the voluntary hospitals object, states—

"Hospitals shall render bills for board and room accommodations, medical and surgical supplies, nursing facilities, and routine laboratory service. Bills for all services rendered by physicians in hospitals, including physiotherapy, x-ray, pathology, anesthesia, medical and surgical care, etc., shall be made out separately and paid directly to the doctor rendering the service. Proper reimbursement by the physician to the hospital for materials and the use of facilities will not be in violation of Section 13-d-2(e)."

Under point 3, the hospitals state—

"To support a claim that a radical change in established custom, which is to apply only to compensation cases, was intended by the Legislature in enacting Section 13-f very cogent reasons indeed would have to appear. Not only are such reasons lacking, but, as we shall point out, every consideration of practicability and fairness negatives such a claim."

They then go on to point out that—

"Private philanthropy has provided the means for the purchase and installation of expensive x-ray, laboratory, physiotherapy, and other equipment. . . ."

and then state that—

"As a result of experience, and with the co-operation of the specialists themselves, the sound custom was long since evolved by which the hospitals charged for these special services, compensating the physicians employed therein on a salary or commission basis. This method, assuring continuity and availability of service and efficient control and management of these important departments, is necessitated by the nature of the services and the complicated setup of the departments."

They further state that—

"Under these circumstances the hospitals themselves have every right to determine what shall

be the cost for the use of its equipment and the method of charging and billing for the services it makes possible. Rule 22 even denies to the hospital the right to bill for the use of its own facilities in this connection."

It may be pointed out here that the present methods employed by hospitals for the determination of cost of such service are entirely unsatisfactory and based upon inadequate and improper methods of cost accounting and bookkeeping. The hospitals are only now attempting to determine and set up a satisfactory method of cost accounting and bookkeeping to apply to all institutions so that the real cost of hospital service in its various aspects may be determined.

The allocation back to the hospital of a reasonable amount to cover the cost of service rendered to roentgenologists, anesthetists, physiotherapists, and other physicians employed by the hospitals or giving services gratuitously could easily be agreed upon and with as much assurance of properly compensating the hospitals as the present methods. Beyond this hospitals should not go. They are not, as corporate bodies, allowed to practice medicine and should not be permitted to exploit physicians. All profits over and above the cost of the service should accrue to physicians (x-ray) treating workmen's compensation cases. The medical societies have urged a reasonable method to compensate the hospitals ever since the inception of the new law. The great bar to the adoption has been the difficulty of the hospitals in arriving at their own figures. This should not be brought up as an argument to invalidate the right of the physician to be paid for his services under the provisions of the *Workmen's Compensation Act*.

In 1933 a committee was appointed by Governor Lehman to study and report on the medical aspects of the *Workmen's Compensation Law*. In its report this committee stated that there were abuses over which the medical profession had no control. Among these abuses attention is called to Item 2—

"Reduced charges by hospitals in order to obtain business."

"Hospitals which accept compensation cases at a per diem charge, which is less than the actual cost of hospitalization, meet the losses by diverting funds which have been given for philanthropic purposes."

While this charge cannot be sustained against the majority of voluntary institutions, it is undoubtedly true that certain hospitals do compete against each other for workmen's compensation cases. They are willing to accept them at preferential rates below the actual cost of maintenance of even a so-called ward bed. The hospitals have not been able to agree among themselves on a uniform per diem rate for compensation cases. The charges vary all the way from \$4.50 to \$6.50 per day. The difference is often made up by charging for so-called extras, such as dressings, medicines, laboratory and x-ray service. A physician may be employed part-time or full-time on a salary or commission basis. Any profit that may result in laboratory or x-ray service accrues to the hospital. Another abuse that arises where the physician (roentgenologist) is merely an employee and not directly responsible and paid by the carrier or employer for the service is the difficulty of obtaining adequate medical testimony by the x-ray or laboratory expert for the claimant or the carrier at the time of a hearing before the Depart-

EVERY DISEASE SOONER OR LATER INVOLVES

# Nutrition

Nutritive failure is concomitant in many, if not most, disease states. It must be considered as a leading factor in convalescence, where its purpose is to repair the damage to the nutritive system and restore it to its proper state.

## Four Essentials for Therapy in Nutritive Failure

1. **DIET:** 4,000 calories, 150 gram protein, rich in vitamins and minerals.
2. **BASIC THERAPY:** Thiamine, riboflavin, niacinamide, ascorbic acid, orally.
3. **ADDITIONAL MEDICATION:** Synthetic vitamins as indicated, orally or parenterally.
4. **NATURAL B COMPLEX:** Brewers' Yeast or extract, or rice bran extract, and/or liver extract orally or parenterally.

For basic therapy, Squibb Basic Formula Vitamin Tablets provide the factors for intensive therapy. This preparation has a background of proved clinical value.

Each tablet contains:

- 10 mg. Thiamine Hydrochloride
- 50 mg. Riboflavin
- 50 mg. Niacinamide
- 75 mg. Ascorbic Acid

...paper on  
...rehabilitation of 100  
American workers for industry.

*Remember the Name*

## Squibb Basic Formula Vitamin Tablets

In stock price per bottle. Describe a few cases where it was used. The cost per tablet is approximately 10¢.

EACH DAY'S production of Lanteen is dated and stored for several months and is subject to a continuing check for stability and consistency. Such control assures a uniform and reliable product. Control of the efficacy of its products, by latest scientific means, is the constant aim of Lanteen Medical Laboratories.

Lanteen Lilac (Mensinga type diaphragm) is available *on the prescription of a physician.*

Since patients are not mechanically minded, simplicity and ease of handling are prime requisites for continued use. Lanteen Lilac flat spring diaphragm is extremely simple to place—it is collapsible in one plane only. No inserter required.

are available from "a large number of men between 18 and 28 years of age found physically disqualified . . . women; soldiers, discharged from the Army; and men over 30 years of age," the Council points out that these possible sources were taken into consideration in the estimates of reduced enrolments submitted by the deans. The Council says: "It is extremely doubtful whether qualified students in these categories are available in significant numbers at present unless admission standards are drastically reduced . . . While every favorable consideration should and will be given to medical school applications from veterans, it would serve neither the veterans nor the public to admit to medical schools men who do not possess the requisite physical, emotional, mental, and other qualifications.

### Industrial Medical Service for Federal Employees

A BILL to provide industrial medical services for all Federal employees, the current total of whom is about 2,700,000, has been endorsed by officials of the Federal government and a representative of the American Medical Association at hearings before the House District Committee.

Surgeon General Thomas Parran said that the services contemplated would include a good pre-placement examination, including a chest x-ray for tuberculosis, minor medical and dental care, minor care for emotional disturbances, a nutritional effort, checks on environmental factors, such as bad lighting, which causes headaches; studies of records of absenteeism, control of contagion and infection, and some routine care in pregnancy. The program, he estimated, would cost less than 1 per cent per day per public employe.

This plan, Dr. Parran continued, would be administered by the Civil Service Commission in consultation with the United States Public Health Service and in close cooperation with agency heads and personnel services. Further, it "is not socialized medicine," he emphasized, but, on the contrary, would be of benefit to the private physician by relieving him of caring for minor illnesses and referring to him such persons as properly need his help.

Dr. Carl Peterson, secretary of the Council on Industrial Health of the American Medical Association,

"It will not meet the problem of obtaining students from these groups 'to offer them the inducement necessary to study medicine.' Students are impelled to study medicine through a long and complicated series of circumstances involving their whole past education, drives, capacities, emotional and social experiences, and not by offering special inducements [as suggested by General Hershey]."

As for the taking of additional students from those who have spent two years in active service, as was suggested to the Army and the Navy and rejected by them, the Council says that such a plan probably would have resulted in many men being returned from the widespread theaters of military operations and even from this country who would not possess the qualifications for the study of medicine.

said his group would actively support legislation of this description if it followed reasonably well a set of standards for such services as would center around an industrial physician, with reliance being placed on the industrial nurse under medical supervision. Also, he said, it should provide industrial hygiene consultation and include disabilities under employment compensation laws.

Close connection with medical services of the community should be maintained, Dr. Peterson held, along with emphasis on preventive technics. The proposed service, he said, should be founded on good records which reflect the population it serves and the administrative personnel should be adequately paid.

Paul V. McNutt, chairman of the War Manpower Commission, said that the Federal government has taken the lead in recommending industrial health services to industry, but has failed to practice what it preaches, with only "the rudiments of a health service" for its own employees.

Arthur S. Flemming, Civil Service Commissioner, said that government employes lost seven sick days each last year.

The common cold, Dr. Parran said, was the principal single cause of absenteeism. He named next in order "the terrific load many married women are carrying" with a heavy job to do at home as well as at the office.

### Council on Physical Therapy Becomes Council on Physical Medicine

AT THE nineteenth annual meeting of the Council on Physical Therapy during December, 1943, a motion was passed unanimously recommending to the Board of Trustees that the name be changed to the Council on Physical Medicine. At the recent annual session of the American Medical Association in Chicago the Board of Trustees recommended to the House of Delegates, and the House of Delegates acted favorably on this recommendation; as a result, the Council on Physical Therapy has now become the Council on Physical Medicine.

The designation "physical medicine" is a more inclusive term. Physical agents are used not only for therapy but also for diagnosis. Hospital departments of physical medicine, when they employ electric tests for reaction of degeneration or perform such tests as the cold pressor test, are employing physical agents not for therapy but for diagnosis.

The Council has for some time interested itself in certain phases of occupational therapy, which is a

branch of the broad field of physical medicine. The Council was informed that the American Occupational Therapy Association was anxious to have the Council give more attention to occupational therapy. Discussions between representatives of the Council and the American Occupational Therapy Association indicated that the association would welcome the inclusion of occupational therapy under a Council on Physical Medicine.

Under the following definition for physical medicine, the entire field can be covered by a Council on Physical Medicine: Physical medicine includes the employment of the physical and other effective properties of light, heat, cold, water, electricity, massage, manipulation, exercise, and mechanical devices for physical and occupational therapy in the diagnosis and treatment of disease. The Council believed that it would be wise to appoint a special subcommittee of five physicians interested

FOOTWEAR

## SHOES AS THERAPEUTIC AGENTS

No doctor can ignore that shoe therapy is a major factor in the treatment of many foot disorders. In some cases, however, when further medical or surgical treatment is required, the shoes must be adjusted to conform to any changes such treatments make in the shape or size of the feet.

Pediforme shoes are prepared through experienced craftsmen to make the necessary adjustments as prescribed by the orthopedic surgeon or physician in these cases.

With purchases restricted it is readily apparent that substantial shoes, capable of reconstruction or easy adjustment, should be prescribed. For all practical purposes, Pediforme footwear may well be considered in shoe therapy.

in occupational therapy who could help to bring this phase of therapy more fully under direct medical supervision.

Finally, there is definite precedent for the use of the term "physical medicine," which has long been considered the most acceptable term by our British colleagues. The Conjoint Board of the

Royal College of Physicians and the Royal College of Surgeons has just instituted a diploma in physical medicine.

With its new name the Council on Physical Medicine will continue to function as it has always functioned but will devote additional attention to problems of occupational therapy.—*Editorial, J.A.M.A., July 29, 1944*

## County News

### Albany County

Dr. A. M. Chapnick, of Wynantskill, honorably discharged recently from the Army Medical Corps after sixteen months' service, has been appointed assistant in psychiatry and neurology at Albany Hospital and Albany Medical College.

Dr. Chapnick, a graduate of the University of Chicago and the University of London, is town health officer for the Town of North Greenbush, a psychiatrist at the Induction Center in Albany, and physician for District Medical Advisory Board 43 of Selective Service, which covers several upstate counties.\*

### Bronx County

The Bronx County Medical Society is now located at 400 East Fordham Road, Room 620, Bronx 58.

The following physicians are at present holding office in the county society: president, Moses H. Krakow, M.D., 1749 Grand Concourse, Bronx 53; secretary, Goodlatte B. Gilmore, M.D., 2940 Grand Concourse, Bronx 58; treasurer, Joseph A. Landy, M.D., 900 Grand Concourse, Bronx 56.

A testimonial dinner was held recently at the Schnorer Club to honor Dr. William K. Kahrs on the occasion of his fiftieth year in the practice of medicine.

The dinner, arranged by the Pediatric Society, was attended by more than fifty physician friends. Dr. Harry Cohen presided, Dr. Forris Chick was toastmaster, and Dr. Jacob Golomb made the gift presentation. It was a delightful social evening, perhaps because it was so entirely different from the conventional. The speakers, Dr. Nathan B. Van Etten and Dr. Kahrs himself, took those present back fifty years by describing the Bronx when it was a horse-and-buggy village of farms, with limited transportation and limited living conveniences.

Dr. Kahrs was born in New York City on February 5, 1872, but he has been a resident of the Bronx since 1884. In 1894, upon his graduation from Bellevue Medical College, he interned at Fordham Hospital, then the first City Hospital in the Borough, which had opened its doors but two years before. Dr. Kahrs was one of the organizers of Union Hospital, serving as visiting physician on its staff and as a member of its Board of Trustees. During World War I, just about the time that he commenced to devote his practice to internal medicine, he served on the local draft board. He served on the induction board during this war and he continues his interest in Union Hospital as consultant physician and member of its Board of Trustees.

Dr. Kahrs is a charter member of the Bronx County Medical Society.

### Broome County

A citation for distinguished service has been awarded to Dr. Charles R. Seymour of Binghamton by the Alumni Association of Albany Medical College and will be presented to him at an association meeting on September 16 in Albany.

A letter announcing award of the citation declared it was given because of the "more than half century of meritorious service in the cause of humanity that you have given."

A graduate of Albany Medical School in 1892, Dr. Seymour has practiced in Binghamton for more than fifty years.

Twice a president of the Broome County Medical Society, Dr. Seymour was a member of the first staff of Binghamton City Hospital.\*

### Cayuga County

Dr. George B. Adams has resigned as director of the Cayuga County Laboratory, after fourteen years' service, to become director of the laboratory in a 450-bed hospital in Winston-Salem, North Carolina.\*

### Columbia County

Dr. Lewis Gregory Cole, head of the x-ray department of the Hudson City Hospital, recently was given one of the outstanding awards of his profession when the American Gastroenterological Association selected him as the recipient of the Friedenwald Medal. The medal will be presented to Dr. Cole at the next annual banquet of the association at its meeting in the East. Dr. Cole resides in White Plains.\*

### Dutchess County

Dr. Edith Gardner Mead, member of the Poughkeepsie Board of Health, has been appointed full-time medical supervisor of the Poughkeepsie school system to succeed Dr. Helen L. Palliser, whose resignation will become effective on October 1.

Dr. W. W. Wicks, of Pine Plains, was appointed township health officer at the monthly meeting of the town board in July. He will succeed Dr. Ellwood Oliver, who died on July 6.

Dr. Wicks has been a practicing physician in Pine Plains for the past sixteen years. He was born in Scotland, South Dakota, where he received his elementary education. He served as a private during the first World War, and later earned his A.B. at Yale and M.D. at Harvard. He served his internship at the Albany Hospital.\*

### Erie County

The county medical society has organized an emergency physicians' service bureau and a con-

sulting board to provide immediate medical assistance to children showing signs of infantile paralysis.

If the family physician is not available, parents may call the bureau and a doctor will be sent at once. Dr. John W. Kohl, chairman of the society's Public Health Committee, said when the bureau was organized on July 18. General practitioners and specialists were named to the consulting board.\*

The regular meetings of the county society will be resumed on October 24.

#### Essex County

At a meeting of the Medical Society of the County of Essex recently, a motion was adopted to give support to the Essex County Veterans Organization in their efforts to secure a full-time, paid service officer for Essex County, it has been announced by Dr. James E. Glavin, of Port Henry, secretary.

It was further decided that any connected service case should not be considered a welfare problem, but that veterans should be entitled to full and complete care by a veterans' organization.

A committee consisting of Dr. John Miller, of Crown Point, and Dr. Glavin was appointed to work with the American Legion in all matters pertaining to veterans.

The Legion has petitioned the Essex County Board of Supervisors to create the service-officer post in the county and the Board now has the matter under consideration.\*

#### Madison County

The annual midsummer meeting of the county society was held at Sylvan Beach, New York, on Thursday, August 10.

A chicken and frog-legs dinner was served to members and guests of the society at Ron-Nell's Restaurant, Scot-Noose Park, Sylvan Beach, at 6:30 P.M.
